FOREWORD

*If the knowledge is
undigested or simply wrong,
more is not better*

How to communicate and disseminate numerical data effectively in chemical science and technology has been a problem of serious and growing concern to IUPAC, the International Union of Pure and Applied Chemistry, for the last two decades. The steadily expanding volume of numerical information, the formulation of new interdisciplinary areas in which chemistry is a partner, and the links between these and existing traditional subdisciplines in chemistry, along with an increasing number of users, have been considered as urgent aspects of the information problem in general, and of the numerical data problem in particular.

Among the several numerical data projects initiated and operated by various IUPAC commissions, the *Solubility Data Project* is probably one of the most ambitious ones. It is concerned with preparing a comprehensive critical compilation of data on solubilities in all physical systems, of gases, liquids and solids. Both the basic and applied branches of almost all scientific disciplines require a knowledge of solubilities as a function of solvent, temperature and pressure. Solubility data are basic to the fundamental understanding of processes relevant to agronomy, biology, chemistry, geology and oceanography, medicine and pharmacology, and metallurgy and materials science. Knowledge of solubility is very frequently of great importance to such diverse practical applications as drug dosage and drug solubility in biological fluids, anesthesiology, corrosion by dissolution of metals, properties of glasses, ceramics, concretes and coatings, phase relations in the formation of minerals and alloys, the deposits of minerals and radioactive fission products from ocean waters, the composition of ground waters, and the requirements of oxygen and other gases in life support systems.

The widespread relevance of solubility data to many branches and disciplines of science, medicine, technology and engineering, and the difficulty of recovering solubility data from the literature, lead to the proliferation of published data in an ever increasing number of scientific and technical primary sources. The sheer volume of data has overcome the capacity of the classical secondary and tertiary services to respond effectively.

While the proportion of secondary services of the review article type is generally increasing due to the rapid growth of all forms of primary literature, the review articles become more limited in scope, more specialized. The disturbing phenomenon is that in some disciplines, certainly in chemistry, authors are reluctant to treat even those limited-in-scope reviews exhaustively. There is a trend to preselect the literature, sometimes under the pretext of reducing it to manageable size. The crucial problem with such preselection - as far as numerical data are concerned - is that there is no indication as to whether the material was excluded by design or by a less than thorough literature search. We are equally concerned that most current secondary sources, critical in character as they may be, give scant attention to numerical data.

On the other hand, tertiary sources - handbooks, reference books, and other tabulated and graphical compilations - as they exist today, are comprehensive but, as a rule, uncritical. They usually attempt to cover whole disciplines, thus obviously are superficial in treatment. Since they command a wide market, we believe that their service to advancement of science is at least questionable. Additionally, the change which is taking place in the generation of new and diversified numerical data, and the rate at which this is done, is not reflected in an increased third-level service. The emergence of new tertiary literature sources does not parallel the shift that has occurred in the primary literature.

With the status of current secondary and tertiary services being as briefly stated above, the innovative approach of the *Solubility Data Project* is that its compilation and critical evaluation work involve consolidation and reprocessing services when both activities are based on intellectual and scholarly reworking of information from primary sources. It comprises compact compilation, rationalization and simplification, and the fitting of isolated numerical data into a critically evaluated general framework.

The *Solubility Data Project* has developed a mechanism which involves a number of innovations in exploiting the literature fully, and which contains new elements of a more imaginative approach for transfer of reliable information from primary to secondary/tertiary sources. *The fundamental trend of the Solubility Data Project is toward integration of secondary and tertiary services with the objective of producing in-depth critical analysis and evaluation which are characteristic to secondary services, in a scope as broad as conventional tertiary services.*

Fundamental to the philosophy of the project is the recognition that the basic element of strength is the active participation of career scientists in it. Consolidating primary data, producing a truly critically-evaluated set of numerical data, and synthesizing data in a meaningful relationship are demands considered worthy of the efforts of top scientists. Career scientists, who themselves contribute to science by their involvement in active scientific research, are the backbone of the project. The scholarly work is commissioned to recognized authorities, involving a process of careful selection in the best tradition of IUPAC. This selection in turn is the key to the quality of the output. These top experts are expected to view their specific topics dispassionately, paying equal attention to their own contributions and to those of their peers. They digest literature data into a coherent story by weeding out what is wrong from what is believed to be right. To fulfill this task, the evaluator must cover *all* relevant open literature. No reference is excluded by design and every effort is made to detect every bit of relevant primary source. Poor quality or wrong data are mentioned and explicitly disqualified as such. In fact, it is only when the reliable data are presented alongside the unreliable data that proper justice can be done. The user is bound to have incomparably more confidence in a succinct evaluative commentary and a comprehensive review with a complete bibliography to both good and poor data.

It is the standard practice that any given solute-solvent system consists of two essential parts: I. Critical Evaluation and Recommended Values, and II. Compiled Data Sheets.

The Critical Evaluation part gives the following information:

- (i) a verbal text of evaluation which discusses the numerical solubility information appearing in the primary sources located in the literature. The evaluation text concerns primarily the quality of data after consideration of the purity of the materials and their characterization, the experimental method employed and the uncertainties in control of physical parameters, the reproducibility of the data, the agreement of the worker's results on accepted test systems with standard values, and finally, the fitting of data, with suitable statistical tests, to mathematical functions;
- (ii) a set of recommended numerical data. Whenever possible, the set of recommended data includes weighted average and standard deviations, and a set of smoothing equations derived from the experimental data endorsed by the evaluator;
- (iii) a graphical plot of recommended data.

The compilation part consists of data sheets of the best experimental data in the primary literature. Generally speaking, such independent data sheets are given only to the best and endorsed data covering the known range of experimental parameters. Data sheets based on primary sources where the data are of a lower precision are given only when no better data are available. Experimental data with a precision poorer than considered acceptable are reproduced in the form of data sheets when they are the only known data for a particular system. Such data are considered to be still suitable for some applications, and their presence in the compilation should alert researchers to areas that need more work.

The typical data sheet carries the following information:

- (i) components - definition of the system - their names, formulas and Chemical Abstracts registry numbers;
- (ii) reference to the primary source where the numerical information is reported. In cases when the primary source is a less common periodical or a report document, published though of limited availability, abstract references are also given;
- (iii) experimental variables;
- (iv) identification of the compiler;
- (v) experimental values as they appear in the primary source. Whenever available, the data may be given both in tabular and graphical form. If auxiliary information is available, the experimental data are converted also to SI units by the compiler.

Under the general heading of Auxiliary Information, the essential experimental details are summarized:

- (vi) experimental method used for the generation of data;
- (vii) type of apparatus and procedure employed;
- (viii) source and purity of materials;
- (ix) estimated error;
- (x) references relevant to the generation of experimental data as cited in the primary source.

This new approach to numerical data presentation, developed during our four years of existence, has been strongly influenced by the diversity of background of those whom we are supposed to serve. We thus deemed it right to preface the evaluation/compilation sheets in each volume with a detailed discussion of the principles of the accurate determination of relevant solubility data and related thermodynamic information.

Finally, the role of education is more than corollary to the efforts we are seeking. The scientific standards advocated here are necessary to strengthen science and technology, and should be regarded as a major effort in the training and formation of the next generation of scientists and engineers. Specifically, we believe that there is going to be an impact of our project on scientific-communication practices. The quality of consolidation adopted by this program offers down-to-earth guidelines, concrete examples which are bound to make primary publication services more responsive than ever before to the needs of users. The self-regulatory message to scientists of 15 years ago to refrain from unnecessary publication has not achieved much. The literature is still, in 1978, cluttered with poor-quality articles. The Weinberg report (in "Reader in Science Information", Eds. J. Sherrod and A. Hodina, Microcard Editions Books, Indian Head, Inc., 1973, p. 292) states that "admonition to authors to restrain themselves from premature, unnecessary publication can have little effect unless the climate of the entire technical and scholarly community encourages restraint..." We think that projects of this kind translate the climate into operational terms by exerting pressure on authors to avoid submitting low-grade material. The type of our output, we hope, will encourage attention to quality as authors will increasingly realize that their work will not be suited for permanent retrievability unless it meets the standards adopted in this project. It should help to dispel confusion in the minds of many authors of what represents a permanently useful bit of information of an archival value, and what does not.

If we succeed in that aim, even partially, we have then done our share in protecting the scientific community from unwanted and irrelevant, wrong numerical information.

A. S. Kertes

December, 1978

PREFACE

The users of this volume will find (1) the available experimental solubility data of krypton, xenon, and radon gas in liquids as reported in the scientific literature, (2) tables of smoothed mole fraction solubility data for the systems which were studied over a temperature interval and (3) tables of either tentative or recommended solubility data when two or more laboratories reported solubility data over the same range of temperature and pressure for a system. Users have the option of using the experimental values, either directly, or in their own smoothing equations, or of using the smoothed values prepared by the compilers and evaluators. The goal was to cover the literature thoroughly enough so that the user need not do a detailed literature search for krypton, xenon, and radon solubility data prior to 1978.

Some words of explanation are required with respect to units, corrections, smoothing equations, auxiliary data and data sources, nomenclature, and other points. The experimental data are presented in the units found in the original paper. In addition the original data are often converted to other units, especially mole fraction. Temperatures have been converted to Kelvin. In evaluations of solubility data, S.I. units are used.

Only in the past 10 to 15 years have experimental methods for the determination of the solubility of gases in liquids developed to the point where 0.5 percent or better accuracy is attained. Only a small fraction of the literature's gas solubility data are accurate to 0.5 percent. The corrections for non-ideal gas behavior and for expansion of the liquid phase on dissolution of the gas are small and well within the normal experimental error. Thus such corrections were not made for the krypton and xenon gas solubility data at low pressure. For radon gas solubility data the real gas volume of 22,290 cm³ mol⁻¹ at standard conditions was used in the calculation of mole fraction.

Small, often unknown partial pressures, of radioactive krypton, xenon and radon are frequently used in the measurement of Ostwald coefficients. Bunsen coefficients and mole fraction gas solubilities at 101.325 kPa (1 atm) were calculated from the Ostwald coefficient, assuming that the Ostwald coefficient was independent of pressure. This is a reasonable often made assumption. However, it is an assumption, and the Bunsen coefficients and mole fraction solubilities calculated from Ostwald coefficients measured at low unknown partial pressures of radioactive gas should be accepted with caution.

The lack of high accuracy is also the reason that only a two-constant equation is used to smooth and evaluate most of the gas solubility data. A Gibbs energy of solution equation linear in temperature is used

$$\Delta G^\circ / \text{J mol}^{-1} = -RT \ln X_1 = A + BT$$

or in alternate form

$$\ln X_1 = -\Delta G^\circ / RT = -(A/R)/T - (B/R)$$

where A is ΔH° , B is $-\Delta S^\circ$, X_1 is the mole fraction solubility at a gas partial pressure of 101.325 kPa (1 atm), and R is 8.31433 J K⁻¹ mol⁻¹. The constants A and B require five digits to reproduce the mole fraction solubility to three significant figures. Although the constants are given to five digits it is not intended to imply that the values of the changes in enthalpy and entropy of solution are significant to more than two or three digits.

An inconsistency, which we believe is justified, is found with respect to the solubility data in water. Much time and effort was expended in evaluating the solubility data of each gas in water. A recommended equation and table of values are presented. However, for systems which contain water and other solvent compounds such as electrolytes or water miscible polar organic compounds, the experimental gas solubility in water from that paper is given, even when it is at variance with our recommended values. These data of sometimes poorer quality are presented because the author's ratio of gas solubility in water to solubility in the aqueous solution may be more accurate than the solubility itself. This may be especially true of some of the solubility data in aqueous electrolyte solutions.

Solvent density data were often required in making solubility unit conversions. The density data were not directly referenced. The main sources of density data are

- Circular 461 of the U.S. National Bureau of Standards
- American Petroleum Research Project 44 Publications
- The International Critical Tables, Volume III (E.W. Washburn, Editor) McGraw-Hill Co., 1931
- Smow Table, Pure and Applied Chemistry 1976, 45, 1-9
- Thermodynamic Properties of Aliphatic Alcohols, R. C. Wilhoit and B. J. Zwolinski, J. Phys. Chem. Ref. Data 1973, 2, Supplement No. 1
- Organic Solvents, J. A. Riddick and W. B. Bunger (Technique of Chemistry, Volume II, A. Weissberger, Editor) Wiley-Interscience, New York, 1970, 3rd Ed.

The solubility data are supplemented with partial molal volume and calorimetric enthalpy of solution data when they are available.

Chemical Abstracts recommended names and registry numbers were used throughout. Common names are cross referenced to Chemical Abstract recommended names in the index.

The Editor would appreciate users calling errors and omissions to his attention.

The Editor gratefully acknowledges the advice and comments of members of the IUPAC Commission on Equilibrium Data and the Subcommittee on Solubility Data; the cooperation and hard work of the Evaluators and compilers; and the untiring efforts of the typists Peggy Tyler, Carolyn Dowie, and Lesley Flanagan.

Acknowledgment is made to the Donors of the Petroleum Research Fund, administered by the American Chemical Society, for partial support of the compilation and evaluation of the gas solubility data.

THE SOLUBILITY OF GASES IN LIQUIDS

C. L. Young, R. Battino, and H. L. Clever

INTRODUCTION

The Solubility Data Project aims to make a comprehensive search of the literature for data on the solubility of gases, liquids and solids in liquids. Data of suitable accuracy are compiled into data sheets set out in a uniform format. The data for each system are evaluated and where data of sufficient accuracy are available values recommended and in some cases a smoothing equation suggested to represent the variation of solubility with pressure and/or temperature. A text giving an evaluation and recommended values and the compiled data sheets are published on consecutive pages.

DEFINITION OF GAS SOLUBILITY

The distinction between vapor-liquid equilibria and the solubility of gases in liquids is arbitrary. It is generally accepted that the equilibrium set up at 300K between a typical gas such as argon and a liquid such as water is gas-liquid solubility whereas the equilibrium set up between hexane and cyclohexane at 350K is an example of vapor-liquid equilibrium. However, the distinction between gas-liquid solubility and vapor-liquid equilibrium is often not so clear. The equilibria set up between methane and propane above the critical temperature of methane and below the critical temperature of propane may be classed as vapor-liquid equilibrium or as gas-liquid solubility depending on the particular range of pressure considered and the particular worker concerned.

The difficulty partly stems from our inability to rigorously distinguish between a gas, a vapor, and a liquid, which has been discussed in numerous textbooks. We have taken a fairly liberal view in these volumes and have included systems which may be regarded, by some workers, as vapor-liquid equilibria.

UNITS AND QUANTITIES

The solubility of gases in liquids is of interest to a wide range of scientific and technological disciplines and not solely to chemistry. Therefore a variety of ways for reporting gas solubility have been used in the primary literature and inevitably sometimes, because of insufficient available information, it has been necessary to use several quantities in the compiled tables. Where possible, the gas solubility has been quoted as a mole fraction of the gaseous component in the liquid phase. The units of pressure used are bar, pascal, millimeters of mercury and atmosphere. Temperatures are reported in Kelvin.

EVALUATION AND COMPILATION

The solubility of comparatively few systems is known with sufficient accuracy to enable a set of recommended values to be presented. This is true both of the measurement near atmospheric pressure and at high pressures. Although a considerable number of systems have been studied by at least two workers, the range of pressures and/or temperatures is often sufficiently different to make meaningful comparison impossible.

Occasionally, it is not clear why two groups of workers obtained very different sets of results at the same temperature and pressure, although both sets of results were obtained by reliable methods and are internally consistent. In such cases, sometimes an incorrect assessment has been given. There are several examples where two or more sets of data have been classified as tentative although the sets are mutually inconsistent.

Many high pressure solubility data have been published in a smoothed form. Such data are particularly difficult to evaluate, and unless specifically discussed by the authors, the estimated error on such values can only be regarded as an "informed guess".

Many of the high pressure solubility data have been obtained in a more general study of high pressure vapor-liquid equilibrium. In such cases a note is included to indicate that additional vapor-liquid equilibrium data are given in the source. Since the evaluation is for the compiled data, it is possible that the solubility data are given a classification which is better than that which would be given for the complete vapor-liquid data (or vice versa). For example, it is difficult to determine coexisting liquid and vapor compositions near the critical point of a mixture using some widely used experimental techniques which yield accurate high pressure solubility data. For example, conventional methods of analysis may give results with an expected error which would be regarded as sufficiently small for vapor-liquid equilibrium data but an order of magnitude too large for acceptable high pressure gas-liquid solubility.

It is occasionally possible to evaluate data on mixtures of a given substance with a member of a homologous series by considering all the available data for the given substance with other members of the homologous series. In this study the use of such a technique has been very limited.

The estimated error is often omitted in the original article and sometimes the errors quoted do not cover all the variables. In order to increase the usefulness of the compiled tables estimated errors have been included even when absent from the original article. If the error on *any* variable has been inserted by the compiler this has been noted.

PURITY OF MATERIALS

The purity of materials has been quoted in the compiled tables where given in the original publication. The solubility is usually more sensitive to impurities in the gaseous component than to liquid impurities in the liquid component. However, the most important impurities are traces of a gas dissolved in the liquid. Inadequate degassing of the absorbing liquid is probably the most often overlooked serious source of error in gas solubility measurements.

APPARATUS AND PROCEDURES

In the compiled tables brief mention is made of the apparatus and procedure. There are several reviews on experimental methods of determining gas solubilities and these are given in References 1-7.

METHODS OF EXPRESSING GAS SOLUBILITIES

Because gas solubilities are important for many different scientific and engineering problems, they have been expressed in a great many ways:

The Mole Fraction, $X(g)$

The mole fraction solubility for a binary system is given by:

$$X(g) = \frac{n(g)}{n(g) + n(l)}$$

$$= \frac{W(g)/M(g)}{\{W(g)/M(g)\} + \{W(l)/M(l)\}}$$

here n is the number of moles of a substance (an *amount* of substance), W is the mass of a substance, and M is the molecular mass. To be unambiguous, the partial pressure of the gas (or the total pressure) and the temperature of measurement must be specified.

The Weight Per Cent Solubility, wt%

For a binary system this is given by

$$\text{wt\%} = 100 W(g) / \{W(g) + W(l)\}$$

where W is the weight of substance. As in the case of mole fraction, the pressure (partial or total) and the temperature must be specified. The weight per cent solubility is related to the mole fraction solubility by

$$X(g) = \frac{\{wt\%/M(g)\}}{\{wt\%/M(g)\} + \{(100 - wt\%)/M(l)\}}$$

The Weight Solubility, C_w

The weight solubility is the number of moles of dissolved gas per gram of solvent when the partial pressure of gas is 1 atmosphere. The weight solubility is related to the mole fraction solubility at one atmosphere partial pressure by

$$X(g) \text{ (partial pressure 1 atm)} = \frac{C_w M(l)}{1 + C_w M(l)}$$

where $M(l)$ is the molecular weight of the solvent.

The Moles Per Unit Volume Solubility, n

Often for multicomponent systems the density of the liquid mixture is not known and the solubility is quoted as moles of gas per unit volume of liquid mixture. This is related to the mole fraction solubility by

$$X = \frac{n v^O(l)}{1 + n v^O(l)}$$

where $v^O(l)$ is the molar volume of the liquid component.

The Bunsen Coefficient, α

The Bunsen coefficient is defined as the volume of gas reduced to 273.15K and 1 atmosphere pressure which is absorbed by unit volume of solvent (at the temperature of measurement) under a partial pressure of 1 atmosphere. If ideal gas behavior and Henry's law is assumed to be obeyed,

$$\alpha = \frac{V(g)}{V(l)} \frac{273.15}{T}$$

where $V(g)$ is the volume of gas absorbed and $V(l)$ is the original (starting) volume of absorbing solvent. The mole fraction solubility X is related to the Bunsen coefficient by

$$X \text{ (1 atm)} = \frac{\alpha}{\alpha + \frac{273.15}{T} \frac{v^O(g)}{v^O(l)}}$$

where $v^O(g)$ and $v^O(l)$ are the molar volumes of gas and solvent at a pressure of one atmosphere. If the gas is ideal,

$$X = \frac{\alpha}{\alpha + \frac{273.15R}{v^O(l)}}$$

Real gases do not follow the ideal gas law and it is important to establish the real gas law used for calculating α in the original publication and to make the necessary adjustments when calculating the mole fraction solubility.

The Kuenen Coefficient, S

This is the volume of gas, reduced to 273.15K and 1 atmosphere pressure, dissolved at a partial pressure of gas of 1 atmosphere by 1 gram of solvent.

The Ostwald Coefficient, L

The Ostwald coefficient, L, is defined as the ratio of the volume of gas absorbed to the volume of the absorbing liquid, all measured at the same temperature:

$$L = \frac{V(g)}{V(l)}$$

If the gas is ideal and Henry's Law is applicable, the Ostwald coefficient is independent of the partial pressure of the gas. It is necessary, in practice, to state the temperature and total pressure for which the Ostwald coefficient is measured. The mole fraction solubility, X, is related to the Ostwald coefficient by

$$X = \left[\frac{RT}{P(g) L v^O(l)} + 1 \right]^{-1}$$

where P is the partial pressure of gas. The mole fraction solubility will be at a partial pressure of P(g).

The Absorption Coefficient, β

There are several "absorption coefficients", the most commonly used one being defined as the volume of gas, reduced to 273.15K and 1 atmosphere, absorbed per unit volume of liquid when the total pressure is 1 atmosphere. β is related to the Bunsen coefficient by

$$\beta = \alpha(1 - P(l))$$

where P(l) is the partial pressure of the liquid in atmosphere.

The Henry's Law Constant

A generally used formulation of Henry's Law may be expressed as

$$P(g) = K_H X$$

where K_H is the Henry's Law constant and X the mole fraction solubility. Other formulations are

$$P(g) = K_2 C(l)$$

or

$$C(g) = K_C C(l)$$

where K_2 and K_C are constants, C the concentration, and (l) and (g) refer to the liquid and gas phases. Unfortunately, K_H , K_2 and K_C are all sometimes referred to as Henry's Law constants. Henry's Law is a limiting law but can sometimes be used for converting solubility data from the experimental pressure to a partial gas pressure of 1 atmosphere, provided the mole fraction of the gas in the liquid is small, and that the difference in pressures is small. Great caution must be exercised in using Henry's Law.

The Mole Ratio, N

The mole ratio, N, is defined by

$$N = n(g)/n(l)$$

Table 1 contains a presentation of the most commonly used inter-conversions not already discussed.

For gas solubilities greater than about 0.01 mole fraction at a partial pressure of 1 atmosphere there are several additional factors which must be taken into account to unambiguously report gas solubilities. Solution densities or the partial molar volume of gases must be known. Corrections should be made for the possible non-ideality of the gas or the non-applicability of Henry's Law.

TABLE 1 Interconversion of parameters used for reporting solubility

$$\begin{aligned}
 L &= \alpha(T/273.15) \\
 C_w &= \alpha/v_o \rho \\
 K_H &= \frac{17.033 \times 10^6 \rho_{\text{soln}}}{\alpha M(l)} + 760 \\
 L &= C_w v_{t,\text{gas}} \rho
 \end{aligned}$$

where v_o is the molal volume of the gas in $\text{cm}^3 \text{mol}^{-1}$ at 0°C , ρ the density of the solvent at the temperature of the measurement, ρ_{soln} the density of the solution at the temperature of the measurement, and $v_{t,\text{gas}}$ the molal volume of the gas ($\text{cm}^3 \text{mol}^{-1}$) at the temperature of the measurement.

SALT EFFECTS

The effect of a dissolved salt in the solvent on the solubility of a gas is often studied. The activity coefficient of a dissolved gas is a function of the concentration of all solute species (see ref. 8). At a given temperature and pressure the logarithm of the dissolved gas activity coefficient can be represented by a power series in C_s , the electrolyte concentration, and C_i , the nonelectrolyte solute gas concentration

$$\log f_i = \sum_{m,n} k_{mn} C_s^m C_i^n$$

It is usually assumed that only the linear terms are important for low C_s and C_i values when there is negligible chemical interaction between solute species.

$$\log f_i = k_s C_s + k_i C_i$$

where k_s is the salt effect parameter and k_i is the solute-solute gas interaction parameter. The dissolved gas activity is the same in the pure solvent and a salt solution in that solvent for a given partial pressure and temperature

$$a_1 = f_i S_i = f_i^o S_i^o \text{ and } f_1 = f_1^o \frac{S_1^o}{S_1}$$

where S_i and S_i^o are the gas solubility in the salt solution and in the pure solvent, respectively, and the f 's are the corresponding activity coefficients. It follows that $\log \frac{f_1}{f_1^o} = \log \frac{S_1^o}{S_1} = k_s C_s + k_i (S_i - S_i^o)$. When the

quantity $(S_i - S_i^o)$ is small the second term is negligible even though k_s and k_i may be of similar magnitude. This is generally the case for gas solubilities and the equation reduces to

$$\log \frac{f_i}{f_i^o} = \log \frac{S_i^o}{S_i} = k_s C_s$$

which is the form of the empirical Setschenow equation in use since the 1880's. A salt that increases the activity coefficient of the dissolved gas is said to salt-out and a salt that decreases the activity coefficient of the dissolved gas is said to salt-in.

Although salt effect studies have been carried out for many years, there appears to be no common agreement of the units for either the gas solubility or the salt concentration. Both molar (mol dm^{-3}) and molal (mol kg^{-1}) are used for the salt concentration. The gas solubility ratio S_i^o/S_i is given as Bunsen coefficient ratio and Ostwald coefficient ratio,

which would be the same as a molar ratio; Kueunen coefficient ratio, volume dissolved in 1 g or 1 kg of solvent which would be a molal ratio; and mole fraction ratio. Recent theoretical treatments use salt concentration in mol dm^{-3} and S_i^0/S_i ratio as mole fraction ratio with each salt ion acting as a mole. Evaluations which compare the results of several workers are made in the units most compatible with present theory.

TEMPERATURE DEPENDENCE OF GAS SOLUBILITY

In a few cases it has been found possible to fit the mole fraction solubility at various temperatures using an equation of the form

$$\ln x = A + B / (T/100K) + C \ln (T/100K) + DT/100K$$

It is then possible to write the thermodynamic functions $\overline{\Delta G}_1^0$, $\overline{\Delta H}_1^0$, $\overline{\Delta S}_1^0$ and $\overline{\Delta C}_{p1}^0$ for the transfer of the gas from the vapor phase at

101,325 Pa partial pressure to the (hypothetical) solution phase of unit mole fraction as:

$$\overline{\Delta G}_1^0 = -RAT - 100 RB - RCT \ln (T/100) - RDT^2/100$$

$$\overline{\Delta S}_1^0 = RA + RC \ln (T/100) + RC + 2 RDT/100$$

$$\overline{\Delta H}_1^0 = -100 RB + RCT + RDT^2/100$$

$$\overline{\Delta C}_{p1}^0 = RC + 2 RDT/100$$

In cases where there are solubilities at only a few temperatures it is convenient to use the simpler equations

$$\overline{\Delta G}_1^0 = -RT \ln x = A + BT$$

in which case $A = \overline{\Delta H}_1^0$ and $-B = \overline{\Delta S}_1^0$.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Krypton; Kr; 7439-90-9 2. Water; H₂O; 7732-18-5 	<p>EVALUATOR:</p> <p>Rubin Battino, Department of Chemistry, Wright State University Dayton, Ohio, 45431 U.S.A. June 1978</p>
<p>CRITICAL EVALUATION:</p> <p>The experimental solubility data produced by three workers was considered to be of sufficient reliability to use for the smoothing equation. In fitting the data to the equation those points which were different by about two standard deviations or more from the smoothed values were rejected. Most of the low temperature values of Morrison and Johnstone were thrown out, but since they had the only higher temperature data these were retained. The transition between their high temperature data and the more reliable low temperature data of the other two workers was smooth. We used 30 points for the final smoothing and they were obtained as follows (reference - number of data points used from that reference): 1-8; 2-6; 3-16. The fitting equation used was</p> $\ln x_1 = A + B/(T/100K) + C \ln (T/100K) + DT/100K \quad (1)$ <p>where x_1 is the mole fraction solubility of krypton at 101,325 Pa (1 atm) partial pressure of gas. The fit in $\ln x_1$ gave a standard deviation of 0.32% taken at the middle of the temperature range. Table 1 gives the smoothed values of the mole fraction solubility (at 101,325 Pa partial pressure of gas) and the Ostwald coefficient at 5K intervals.</p> <p>Table 1 also gives the thermodynamic functions $\Delta \bar{G}_1^\circ$, $\Delta \bar{H}_1^\circ$, $\Delta \bar{S}_1^\circ$, $\Delta \bar{C}_{p1}^\circ$ for the transfer of gas from the vapor phase at 101,325 Pa partial gas pressure to the (hypothetical) solution phase of unit mole fraction. These thermodynamic properties were calculated from the smoothing equation according to the following equations:</p> $\Delta \bar{G}_1^\circ = -RAT - 100RB - RCT \ln (T/100) - RDT^2/100 \quad (2)$ $\Delta \bar{S}_1^\circ = RA + RC \ln (T/100) + RC + 2RDT/100 \quad (3)$ $\Delta \bar{H}_1^\circ = -100RB + RCT + RDT^2/100 \quad (4)$ $\Delta \bar{C}_{p1}^\circ = RC + 2RDT/100 \quad (5)$ <p>The best fit for the 30 data points gave the following equation</p> $\ln x_1 = -66.9928 + 91.0166/(T/100K) + 24.2207 \ln (T/100K) \quad (6)$ <p>The data from six other workers were rejected for the following reasons. Yeh and Peterson's values (4) were 3 to 4 per cent low. Antropoff's data (5) were very far off, being all much too low. König's results (6) were also low, being off by about 4 to 12 per cent. The two values by Van Liempt (7) were rather imprecise. Kitani (8) determined the solubility of krypton-85 in water, saline, lipids and blood at 37°C by a radiochemical technique. Seventeen determinations at the one temperature were reproducible to $\pm 4\%$ and were 5% lower than the selected values in this section. Wood and Caputi (9) determined the solubilities from 1 to 48°C in water and sea water, but their results are 2 to 5% high.</p>

Wright State University
Dayton, Ohio 45431
U.S.A.

June 1978

CRITICAL EVALUATION:

Anderson, Keeler, and Klach (10) measured the solubility of krypton + krypton-85 between 373 and 573K at partial pressures of 1.5 to 60×10^{-4} psia in the presence of oxygen gas at pressures between 270 and 1930 psia. The mole fraction solubility calculated at 101.325 kPa krypton partial pressure appears to be a consistent extension of the krypton solubilities below 353K. The combined data indicates the minimum solubility is at 380 K. See the data sheets for the Anderson, Keeler and Klach paper for additional information.

Alexander (11) made seven determinations of the heat of solution of krypton in water at 298.15 K. He obtained an enthalpy of solution of $-(15.8_2 \pm 0.6_8) \text{ kJ mol}^{-1}$. The value agrees well with the value of $-15.63 \text{ kJ mol}^{-1}$ derived from the solubility data.

Popov and Drakin (12, 13) measured the apparent molar volume of krypton dissolved in water under a krypton partial pressure of 4.7 to 20.1 atm at 298.15 K by a density method.

p/atm	4.70	12.00	15.20	18.27	20.10
$\bar{V}/\text{cm}^3 \text{ mol}^{-1}$	38 ± 5	32 ± 2	31.2 ± 1.4	31.4 ± 1.2	31.3 ± 1.1

They recommended a value of $31.3 \text{ cm}^3 \text{ mol}^{-1}$.

AUXILIARY INFORMATION																																																																
METHOD / APPARATUS / PROCEDURE: Gas-free water and the pure gas are equilibrated, and volumetric samples of the liquid and gaseous phases are isolated. The gas dissolved in the water is extracted and the number of moles determined on a special mercury manometer. After removal of the water vapor, the number of moles in the sample of the gaseous phase is measured with the same manometer; from which the pressure (and fugacity) above the solution may be calculated. Real gas corrections are made. Predicted maximum error is 0.02%. No drawings of the apparatus are given in the original paper.	SOURCE AND PURITY OF MATERIALS: 1. Krypton. Matheson Gas Products. greater than 99.995 % pure. Gas chromatographic checks showed less than 0.01 % air. 2. Water. Distilled.

The mole fraction solubility at a partial pressure of 101.325 kPa krypton was calculated by the compiler.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:	
A Kr/ ⁸⁵ Kr stock mixture and O ₂ are added separately to a thermostated stainless steel vessel containing about 275 ml of water. Equilibration time varied from 1.5 to 22 hours without appreciable difference in results (one run went for 64 hours). At equilibrium both liquid and vapor were sampled and the krypton in each phase was determined by counting the ⁸⁵ Kr tag.				
Henry's law constant is linear in temperature. The authors give K = (p/psia)/X ₁ = (0.126-0.0263 (t/°C)) x 10 ⁵ with a standard deviation of 0.218 x 10 ⁵ .			ESTIMATED ERROR: At the 95% confidence level the uncertainty in K is ± 0.471 x 10 ⁵ (0.0677 - (T - 202) ² /75334) δT/K = 0.1

	Continued from previous page.

Smoothed data: A graph of the krypton mole fraction solubility at a partial krypton pressure of 101.325 kPa was constructed using the solubility data at temperatures between 273 and 348 K used in the critical evaluation of krypton + water, as well as the data from this paper. The data give a single smooth curve with a minimum near 380 K.

The thirty data points used in the critical evaluation of krypton solubility at temperature below 348 K and the 15 data points from the present paper were combined in a linear regression to obtain the equation

$$\ln X_1 = -61.52677 + 82.72769/(T/100) + 21.7672 \ln (T/100)$$

The equation is a tentative equation for use between 373.15 and 573.15 K. It is not recommended for use at lower temperatures. It gives a mole fraction solubility at 273.15 K that is 3.3% lower, at 293.15 K 0.02% lower, and 348.15 K 2.5% higher than the recommended equation for that temperature interval.

Smoothed values of the mole fraction solubility, Ostwald coefficients, Gibbs energy, enthalpy and entropy of solution at 25 K intervals between 373.15 and 573.15 K are given in Table 1. A comparison of the two equations and the data from this paper is given in Figure 1.

TABLE 1. Tentative values of the solubility of krypton in water at a krypton partial pressure of 101.325 kPa and values of the thermodynamic properties on solution between 373.15 and 573.15 K.

T/K	Mol Fraction $X_1 \times 10^5$	Ostwald Coefficient L	$\Delta G^\circ/\text{kJ mol}^{-1}$	$\Delta H^\circ/\text{kJ mol}^{-1}$	$\Delta S^\circ/\text{J K}^{-1}\text{mol}^{-1}$
373.15	2.27	0.0370	33.18	-1.25	-92.3
398.15	2.31	0.0394	35.33	+3.27	-80.5
423.15	2.55	0.0451	37.21	+7.80	-69.5
448.15	2.99	0.0545	38.81	+12.3	-59.1
473.15	3.68	0.0684	40.17	+16.8	-49.3
498.15	4.69	0.0884	41.28	+21.4	-40.0
523.15	6.16	0.116	42.17	+25.9	-31.1
548.15	8.27	0.155	42.84	+30.4	-22.7
573.15	11.3	0.207	43.31	+34.9	-14.6

ΔC_p° is constant with a value of $181. \text{ J K}^{-1} \text{ mol}^{-1}$.

FIGURE 1. The mole fraction solubility of krypton in water at a krypton partial pressure of 101.325 kPa (1 atm). Recommended low temperature equation ----, tentative high temperature equation —.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Krypton; Kr; 7439-90-9 2. Sea Water 	<p>EVALUATOR:</p> <p>H. L. Clever Chemistry Department Emory University Atlanta, GA 30322 U.S.A.</p>
<p>CRITICAL EVALUATION:</p> <p>There are three reports of the solubility of krypton in sea water. König (1) reports krypton solubility values at eight temperatures between 273.15 and 297.15 K. Wood and Caputi (2) report krypton solubility values at three temperatures between 274.45 and 321.25 K. Weiss and Kyser (3) report three to five krypton solubility values at each of seven temperatures between 273.23 and 313.25 K.</p> <p>Weiss and Kyser appear to have carried out the most reliable work and we recommend use of their values. Weiss and Kyser corrected these data for the real molar value of krypton and for the fugacity of the krypton. Their equation for the Bunsen solubility coefficient of krypton, corrected for nonideal behavior, is given by the equation</p> $\ln[\text{Bunsen}] = -57.2596 + 87.4242(100/T) + 22.9332 \ln(T/100) + S\%[-0.008723 - 0.002793(T/100) + 0.0012398(T/100)^2]$ <p>where T is the absolute temperature and S% is the salinity in parts per thousand.</p> <p>Weiss and Kyser give equations for the solubility of krypton from moist air at 101.325 kPa (1 atm) total pressure in units of $\text{cm}^3 \text{ Kr(STP)} \text{ dm}^{-3}$ sea water and $\text{cm}^3 \text{ Kr(STP)} \text{ kg}^{-1}$ sea water assuming that krypton mole fraction in dry air is 1.141×10^{-6} (4). The equations are</p> $\ln[\text{cm}^3 \text{ Kr(STP)} \text{ dm}^{-3}] = -109.9320 + 149.8152(100/T) + 72.8393 \ln(T/100) - 9.9217(T/100) + S\%[-0.006953 - 0.004085(T/100) + 0.0014759(T/100)^2]$ <p>and</p> $\ln[\text{cm}^3 \text{ Kr(STP)} \text{ kg}^{-1}] = -112.6840 + 153.5817(100/T) + 74.4690 \ln(T/100) - 10.0189(T/100) + S\%[-0.011213 - 0.001844(T/100) + 0.0011201(T/100)^2]$ <p>Extensive tables of krypton Bunsen coefficients and $\text{cm}^3 \text{ Kr(STP)} \text{ kg}^{-1}$ as a function of temperature and salinity as calculated from the above equations are given in the original paper.</p> <p>Weiss and Kyser compare the earlier work with their results. They show that the König data are as much as 14 per cent lower at low temperatures and that the Wood and Caputi data averages 1.9 percent lower than their own data at 274.45 and 299.55 K. Data sheets follow for both the Weiss and Kyser and the Wood and Caputi solubility values. The Wood and Caputi values extend the temperature range another seven degrees.</p> <ol style="list-style-type: none"> 1. König, H. <u>Z. Naturforsch.</u> 1963, 18a, 363. 2. AUXILIARY INFORMATION					
METHOD: Solubility determinations by the Scholander microgasometric technique as used by Douglas (1), with minor modification by Weiss (2). Real krypton molar volume at STP was used and a fugacity correction was applied.			SOURCE AND PURITY OF MATERIALS: 1. Krypton. Matheson Gas Products. > 99.995 % pure. Gas chromatographic checks showed ≤ 0.01 % air. 2. Sea Water. Collected from surface, evaporated to increase salinity ~ 2‰, passed through 0.45 μ millipore filter and poisoned with 1 mg/l of HgCl ₂ .		
APPARATUS/PROCEDURE: An equilibrium chamber, containing pure gas saturated with water vapor, is separated by mercury from a closed side chamber containing degassed water. The apparatus is tipped on its side, allowing degassed water to flow into the equilibrium chamber. Dissolution is aided by mechanical shaking.			ESTIMATED ERROR: δT/K = 0.01 δsalinity = 0.004

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
<p>Degassed water was introduced into an evacuated apparatus (< 50 μ Hg) and gas bled into burette. After the system was isolated, gas was admitted to equilibrium column and the water was circulated through the column, flowing over packing of 4 mm Berl saddles at 110 ml/min for 4-5 hr.</p> <p>Dissolved gas was reclaimed and measured by evacuating the system \rightarrow < 1 μ Hg and allowing water to distill and condense in a cold trap. Water was melted and refrozen until all the gas was recovered. Gas was then transferred to a gas burette and the pressure was measured with a Hg manometer. Purity was checked by gas chromatography.</p>			1. Krypton. AIRCO. Certified 0.015% Xe. Air contamination 0.0001 determined by gas chromatography. 2. Water. Distilled three times before degassing. Sea Water. Artificial, modified from (1).

<p>CRITICAL EVALUATION:</p> <p>The solubility of krypton in aqueous electrolyte solutions.</p> <p>The results of studies of the solubility of krypton in aqueous salt solution can be classified as no better than tentative. Körösy (1) reports a solubility of krypton in aqueous 20 weight per cent CaCl₂ solution which is of dubious value. Morrison and Johnstone (2) report Setschenow salt effect parameters for 13 aqueous electrolyte solutions. All of their values are based on only one measurement in a one molal salt solution. Although Morrison and Johnstone's Setschenow parameter values for other gases usually accord well with the results of more extensive studies of other workers, their values based on only one measurement in an electrolyte solution must be classed as tentative.</p> <p>Yeh and Peterson (3), Kitani (4), and Kirk, Parrish and Morken (5) have measured the solubility of krypton in 0.9 weight percent NaCl solution. Kirk et al. did not report a krypton solubility in water so it is not possible to convert their solubility value to a Setschenow parameter. The Setschenow salt effect parameters for krypton in aqueous NaCl solutions from the data of Morrison and Johnstone, Yeh and Peterson, and Kitani do not agree well (Table 1). The values based on Yeh and Peterson's data appear to be high and somewhat erratic as a function of temperature. The values of Morrison and Johnstone and of Kitani are probably more reliable.</p> <p>Anderson, Keeler and Klach (6) measured the solubility of krypton in water, and in aqueous solution containing UO₂SO₄, CuSO₄ and H₂SO₄ at temperatures between 373 and 573 K. They found no statistical difference in the Henry's constant of krypton in water and in a solution that was 0.02 mol dm⁻³ UO₂SO₄, 0.005 mol dm⁻³ CuSO₄ and 0.005 mol dm⁻³ H₂SO₄. There were differences in the Henry's constant for krypton in water and in a little more concentrated solution containing 0.04 mol dm⁻³ UO₂SO₄, 0.01 mol dm⁻³ CuSO₄ and 0.01 mol dm⁻³ H₂SO₄.</p>	

COMPONENTS:

The mole fraction solubility at a krypton partial pressure of 101.325 kPa was calculated by the compilers.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

A Kr/⁸⁵Kr stock mixture and O₂ are added separately to a thermostated stainless steel vessel containing about 275 ml of solution. Equilibration time varied from 1.5 to 22 hours without appreciable difference in results (one run went for 64 hours). At equilibrium both liquid and vapor were sampled and the krypton in each phase was determined by counting the ⁸⁵Kr tag.

Henry's law constant is not linear in temperature as it appears to be for water and the more dilute uranyl sulfate solution.

The mean values of K at the four temperatures are

T/K	K/psia X ₁ ⁻¹ x 10 ⁻⁵
373.15	(6.16 ± 0.26)
423.15	(5.36 ± 0.26)
473.15	(2.06 ± 0.23)
523.15	(1.09 ± 0.23)

SOURCE AND PURITY OF MATERIALS:

No information

ESTIMATED ERROR:

The values of the Setschenow salt effect parameter, k_s , were apparently determined from only two solubility measurements. They were the solubility of krypton in pure water, S^0 , and the solubility of krypton in a near one equivalent of salt per kg of water solution, S . No solubility values are given in the paper. The S^0/S ratio was referenced to a solution containing one kg of water. The compiler calculated the salt effect parameter k_{sX} from the mole fraction solubility ratio X^0/X . The electrolytes were assumed to be 100 per cent dissociated and both cation and anion were used in the mole fraction calculation.

EVALUATOR:

H. L. Clever
Chemistry Department
Emory University
Atlanta, GA 30322
U.S.A.

CRITICAL EVALUATION:

The solubility of krypton in hexane at 101.325 kPa was measured in three laboratories. Clever, Battino, Saylor and Gross (1) report three solubilities between 289.30 and 313.75 K. Steinberg and Manowitz (2) report solubilities at 183.15 and 298.15 K. Makranczy, Megyery-Balog, Ruzs, and Patyi (3) report a solubility at 298.15. The solubility values near 298.15 K from the three laboratories differ by about 30 percent.

Clever *et al.* probably used materials of better purity than the materials used by Steinberg and Manowitz. The single value of Makranczy *et al.* is difficult to judge, but their results tend to scatter for other gases dissolved in hydrocarbons. The values of Clever *et al.* are to be preferred for the 288.15 - 313.15 K temperature range. The smoothed data is given on the Clever *et al.* data sheet which follows this page.

The 183.15 K solubility value of Steinberg and Manowitz and the three solubility values of Clever *et al.* were combined in a linear least squares fit to an equation for the Gibbs energy of solution as a function of temperature. The result is a highly tentative equation for the 183.15 - 313.15 K temperature interval.

The tentative values for the transfer of one mole of krypton from the gas at a pressure of 101.325 kPa to the hypothetical unit mole fraction solution are

$$\Delta G^\circ / J \text{ mol}^{-1} = -RT \ln X_1 = -3,340.9 + 52.564 T$$

$$\text{Std. Dev. } \Delta G^\circ = 63, \quad \text{Coef. Corr.} = 0.9998$$

$$\Delta H^\circ / J \text{ mol}^{-1} = -3,340.9, \quad \Delta S^\circ / J \text{ K}^{-1} \text{ mol}^{-1} = -52.564$$

The tentative solubility values and the Gibbs energy of solution at 101.325 kPa as a function of temperature are in Table 1.

TABLE 1. Solubility of krypton in hexane. Tentative values of the mole fraction solubility and Gibbs energy at 101.325 kPa (1 atm) as a function of temperature.

T/K	Mol Fraction $X_1 \times 10^3$	$\Delta G^\circ / J \text{ mol}^{-1}$

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Krypton; Kr; 7439-90-9 2. Octane; C₈H₁₈; 111-65-9 <p>Decane; C₁₀H₂₂; 124-18-5</p>	<p>EVALUATOR:</p> <p>H. L. Clever Chemistry Department Emory University Atlanta, GA 30322 U. S. A.</p> <p>October 1978</p>
<p>CRITICAL EVALUATION:</p> <p>Solubilities in the octane + krypton and decane + krypton systems were reported from three laboratories. Clever, Battino, Saylor and Gross (1) reported solubility values at three temperatures between 289 and 313 K. Both Makranczy, Megyery-Balog, Rusz and Patyi (2) and Wilcock, Battino, Danforth and Wilhelm (3) report one value at or very near 298.15 K.</p> <p>Octane + Krypton</p> <p>The solubility values of krypton in octane from the three laboratories at 298.15 K shows a range of values of 3.8 per cent. The value of Wilcock, <u>et al.</u> (3), determined with improved apparatus for degassing and solubility measurement, should be the most reliable value. However, since they report a solubility at only one temperature, we recommend as the tentative values the data of Clever, <u>et al.</u> (2) (Page 36) with the reservation that the smoothed value at 298.15 K may be about one percent high.</p> <p>Decane + Krypton</p> <p>The solubility values for krypton in decane at 298.15 K from the three laboratories shows a 4.3 per cent range. The average value from the three laboratories agrees within 0.2 per cent of the value of Clever, <u>et al.</u> (2). We recommend as the tentative solubility values the smoothed data of Clever, <u>et al.</u> (2) (Page 40). The single value of Wilcock, <u>et al.</u> (3) at 298.16 K is 2 per cent higher and may be the most reliable experimental value.</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. Clever, H. A preliminary account of this work appeared in <u>Conf. Int. Thermodyn. Chim.</u> (C.R.) 4th 1975, 6, 122-128.			
The solubility value was adjusted to a partial pressure of krypton of 101.325 kPa (1 atm) by Henry's law.			
The Bunsen coefficient was calculated by the compiler.			
See the evaluation of krypton + octane for the recommended Gibbs energy equation and smoothed solubility values.			
AUXILIARY INFORMATION			
METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		1. Krypton. The Matheson Co., Inc., or Air Products and Chemicals. Purest commercially available. 2. Octane. Phillips Petroleum Co. 99 mol per cent minimum.

The solubility values were adjusted to a partial pressure of krypton of 101.325 kPa (1 atm) by Henry's law.			
The Bunsen coefficients were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Solvent was degassed by a modification of the method of Baldwin and Daniel (1). Saturation apparatus was that of Morrison and Billett (2), modified to include spiral storage for the solvent, a manometer for constant reference pressure, and an extra buret. Solvent was saturated with gas as it flowed through an 8 mm x 180 cm glass spiral attached to a buret.		1. Krypton. Linde Air Products Co. Pure.	
		2. Decane. Humphrey-Wilkinson, Inc. Shaken with H ₂ SO ₄ , washed, dried over Na.

Steinberg and Manowitz, and Makranczy, Megyery-Balog, Ruzs, and Patyi each report a krypton in dodecane solubility value at 298.15 K (see next two pages). The tentative recommendation is to use the data above.			
The Bunsen coefficients were calculated by the compiler. Solubility values were corrected to a krypton partial pressure of 101.325 kPa by Henry's law.			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
Volumetric. The solvent is saturated with gas as it flows through an 8 mm x 180 cm glass helix attached to a gas buret. The total pressure of solute gas plus solvent vapor is maintained at 1 atm as the gas is absorbed.		1. Krypton. Linde Air Products Co.	
		2. Dodecane. Humphrey-Wilkinson, Inc. Shaken with conc. H ₂ SO ₄ , water washed, dried over Na.	
APPARATUS/PROCEDURE:		ESTIMATED ERROR:	
The apparatus is a modification of the apparatus of Morrison and Billett (1). The modifications include the addition of a helical storage for the solvent, a manometer for a reference pressure, and an extra buret for highly soluble gases. The solvent is degassed by a modification of the method of Baldwin and Daniel (2).		δT/K = 0.05	
		δP/mmHg = 3	
		δx ₁ /x ₁ = 0.03	
		REFERENCES:

EVALUATOR:

H.L. Clever
Chemistry Department
Emory University
Atlanta, GA 30322
U.S.A.

CRITICAL EVALUATION:

The solubility of krypton in cyclohexane at 101.325 kPa was measured in two laboratories. Clever, Battino, Saylor and Gross (1) report three values between 289.15 and 313.65 K. Dymond (2) reports four values between 293.50 and 309.35 K. Each data set was fitted to a Gibbs energy equation linear in temperature by the method of least squares. The smoothed data agreed within 1.7 per cent at 293.15 K and 0.5 per cent at 313.15 K, with the Dymond solubility values being the higher values over the temperature range. The two data sets agree well within experimental error.

The seven solubility values from the two laboratories were combined and fitted to a Gibbs energy equation linear in temperature by the method of least squares to obtain the recommended equation.

The recommended thermodynamic values for the transfer of krypton from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are

$$\Delta G^{\circ}/\text{J mol}^{-1} = -RT \ln X_1 = -3,576.0 + 56.557 T$$

$$\text{Std. Dev. } \Delta G^{\circ} = 15, \text{ Coef. Corr.} = 0.9995$$

$$\Delta H^{\circ}/\text{J mol}^{-1} = -3,576.0, \Delta S^{\circ}/\text{J K}^{-1} \text{ mol}^{-1} = -56.557$$

The recommended values of the mole fraction solubility at 101.325 kPa and the Gibbs energy of solution as a function of temperature are given in Table 1.

TABLE 1. Solubility of krypton in cyclohexane.
Recommended mole fraction solubility and
Gibbs energy of solution as a function
of temperature.

AUXILIARY INFORMATION									
METHOD: The apparatus and method of Winkler (1) were used. However, the apparatus was usually not thermostated, and de-gassing was by evacuating and shaking the solvent, not by evacuating and boiling the solvent as was done by Winkler.	SOURCE AND PURITY OF MATERIALS: 1. Krypton. Source not given. The gas contained 5% xenon and 1% non-inert gases. 2. 1,2,3,4-Tetrahydronaphthalene. No information.								
APPARATUS/PROCEDURE:	ESTIMATED ERROR: $\delta x_1/x_1 = 0.05$ REFERENCES: 1. Winkler, L.W. <u>Ber.</u> 1891, <u>24</u> , 89.

The Bunsen coefficients were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Solvent was degassed by a modification of the method of Baldwin and Daniel (1). Saturation apparatus was that of Morrison and Billett (2), modified to include spiral storage for the solvent, a manometer for constant reference pressure, and an extra buret. Solvent was saturated with gas as it flowed through an 8 mm x 180 cm glass spiral attached to a buret.		1. Krypton. Linde Air Products Co. Pure.	
		2. Benzene. Jones & Laughlin Steel Co. Shaken with H ₂ SO ₄ , water washed, dried over Na, distilled.	
NOTE: F. Körösy Trans. Faraday Soc. 1937, <u>33</u> , 416 reports an Ostwald coefficient of 0.97 (mole fraction 3.55×10^{-3}) at 295.15 K. Van Liempt and van Wijk Recl. trav. Chim. Pays-Bas 1937, <u>56</u> , 632 report a Bunsen coefficient of 0.67 (mole fraction 2.65×10^{-3}) at 292.15 K. Neither of the solubility of krypton in benzene values were considered in the smoothed data fit given above.		ESTIMATED ERROR:	
		$\delta T/\text{K} = 0.05$	
		$\delta P/\text{mmHg} = 3$	
		$\delta x_1/x_1 = 0.03$

AUXILIARY INFORMATION																															
METHOD /APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																														
The solvent was degassed by evacuating the space above it, shaking, and then passing it as a fine mist into another evacuated container. The degassed liquid was saturated as it passed as a thin film inside a glass helix which contained the solute gas plus solvent vapor at a total pressure of 1 atm (1,2). The volume of liquid and the volume of gas absorbed are determined in a system of burets.	1. Krypton. Matheson Co., Inc. Research grade. 2. Toluene. Mallinckrodt. Reagent grade. Shaken over conc. H ₂ SO ₄ , water washed, dried over Drierite, distilled b.p. 110.40 - 110.60° C.																														
Evaluator's Note: Van Liempt and van Wijk Recl. Trav. Chim. Pays-Bas, 1937, 56, 632 report a Bunsen coefficient of 0.84 (mole fraction 4.0 x 10 ⁻³) at 291.15 K for this system. The value is not recommended for use.	ESTIMATED ERROR: δT/K = 0.03 δP/torr = 3 δX ₁ /X ₁ = 0.005

AUXILIARY INFORMATION			
METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus is based on the design by Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent passes in a thin film down a glass spiral tube containing the solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final gas volume in the buret system. The solvent is collected in a tared flask and weighed.		1. Krypton. The authors define the Absorption Coefficient as the volume of gas, corrected to 288.15 K and 101.325 kPa, absorbed under a total system pressure of 101.325 kPa per unit volume of solvent at 288.15 K.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:	
The absorption coefficient at one atm krypton was measured by modified McDaniel method (1). The Henry's constant ($K = (P/\text{atm})/X_1$) at low concentration of krypton was measured by static and dynamic tracer techniques. The authors state that log (Absorption Coefficient) vs $1/T$ is linear and gives an enthalpy of solution of $-1700 \text{ cal mol}^{-1}$.			1. Krypton. Matheson Co., Inc. Technical grade. 2. CRITICAL EVALUATION:

The solubility of krypton in methanol was measured in several laboratories. Only one laboratory reports krypton in methanol solubility values at more than one temperature. Thus, it is not possible to intercompare data from the different laboratories and recommend a set of solubility values and thermodynamic parameters for the system.

Van Liempt and van Wijk (1) report a Bunsen coefficient of 0.52 (mole fraction 0.94×10^{-3}) at 291.15 K. Steinberg and Manowitz (2) report an absorption coefficient (volume of gas corrected to 288.15 K and 101.325 kPa absorbed under a total system pressure of 101.325 kPa per unit volume of solvent calculated at 288.15 K) of 1.06 at 144.15 to 153.15 K in the methanol + water eutectic (83 weight percent methanol). Komarenko and Manzhelii (3) report five solubility values between 176.15 and 213.15 K measured at a krypton pressure of 26.664 kPa (200 mmHg). The compiler has recalculated these at 101.325 kPa assuming Henry's law is obeyed.

It is not possible to judge the reliability of the single solubility values of van Liempt and van Wijk and of Steinberg and Manowitz. Data sheets on them are not included. Both the methanol and the krypton used by Komarenko and Manzhelii are of exceptional purity. Their degassing technique is thorough. The solubility method appears reliable, and their data should be of good quality. The Komarenko and Manzhelii solubility values were fitted to a three constant equation by the method of least squares. The smoothed solubility values at 101.325 kPa and the values of the thermodynamic changes for the transfer of krypton from the gas at 101.325 kPa to the hypothetical unit mole fraction solution for the temperature interval of 173.15 to 213.15 K are given on the data sheet which follows.

Although recommended solubility of krypton in methanol values are not given, a tentative set of values based on the five low temperature values of Komarenko and Manzhelii and the single room temperature value of von Liempt and van Wijk is given. This set of values should be used with extreme caution until more work is done on the system. The solubility equation is

$$\ln x_1 = -12.625 + 11.868/(T/100) + 1.4776 \ln (T/100)$$

Solubility values and values of thermodynamic parameters are given in Tables 1 and 2.

The mole fraction solubility at 101.325 kPa (760 mmHg) was calculated by Henry's law by the compiler.					
AUXILIARY INFORMATION					
METHOD / APPARATUS / PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
The solvent was degassed by vacuum. A thin layer of alcohol, cooled to 125-175 K, was kept for 20 hours in a vacuum maintained at 10 ⁻³ mmHg. The degassed liquid was sealed under vacuum in an ampoule which was placed in the apparatus. The apparatus consisted of a manostat, a mercury compensator, and a solubility cell divided by a mercury seal. A gas pressure of 200 mmHg and the temperature were established. The foil ends of the ampoule were pierced. The gas dissolved as the liquid flowed through a series of small cups. The amount of gas dissolved was determined by the rise in mercury level in the compensator. Some measurements were made at 400 mmHg gas pressure. The results confirmed that Henry's law was obeyed.			1. Krypton. Source not given. Purity by chromatographic method was 99.89 per cent. 2. 1-Butanol. Purified and analyzed in the All-Union Sci. Res. Inst. for Single Crystals & High-Purity Substances. Purity 99.97 weight per cent.		
			ESTIMATED ERROR:		
			δT/K = 0.05 δP/mmHg = 0.01 δx ₁ /x ₁ = 0.005

The solubility values were adjusted to a partial pressure of krypton of 101.325 kPa (1 atm) by Henry's law.				
The Bunsen coefficients were calculated by the compiler.				
AUXILIARY INFORMATION				
METHOD:		SOURCE AND PURITY OF MATERIALS:		
Volumetric. The apparatus (1) is a modification of that used by Morrison and Billett (2). Modifications include the addition of a spiral solvent storage tubing, a manometer for constant reference pressure, and an extra gas buret for highly soluble gases.		1. Krypton. Matheson Co., Inc. Both standard and research grades were used.		
		2. Perfluoromethylcyclohexane. du Pont FCS-326, shaken with concentrated H ₂ SO ₄ , washed, dried over Drierite and distilled. b.p. 75.95 to 76.05° at 753 mm., lit. b.p. 76.14 at 760 mm.		
APPARATUS/PROCEDURE:		ESTIMATED ERROR:		
(a) Degassing. 700 ml of solvent is shaken and evacuated while attached to a cold trap, until no bubbles are seen; solvent is then transferred through a 1 mm capillary tubing, released as a fine mist into a continuously evacuated flask. (b) Solvent is saturated with gas as it flows through 8 mm x 180 cm of tubing attached to a gas buret. Pressure is maintained at 1 atm as the gas is absorbed.		δT/K = 0.05 δP/mmHg = 3 δX ₁ /X ₁ = 0.03

The mole fraction solubility and the Bunsen coefficient were calculated by the compiler. It was assumed that gas behavior is ideal, the Ostwald coefficient is independent of pressure, and that Henry's law is obeyed.			
AUXILIARY INFORMATION			
METHOD: The apparatus and method of Winkler (1) were used. However, the apparatus was usually not thermostated, and degassing was by evacuating and shaking the solvent, not by evacuating and boiling the solvent as was done by Winkler.		SOURCE AND PURITY OF MATERIALS: 1. Krypton. Source not given. The gas contained 5% xenon and 1% non-inert gases. 2. Solvents. No information.

AUXILIARY INFORMATION																							
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																					
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred and the vacuum is applied intermittently through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		1. Krypton. Either Air Products & Chemicals or Matheson. Better than 99 mol % (usually 99.9+) 2. Hexafluorobenzene. Imperial Smelting Co., Avonmouth, U.K. GC purity 99.7%, density at 25° C 1.60596 g cm ⁻³ . AUXILIARY INFORMATION																					
METHOD: Volumetric. The solvent is saturated with gas as it flows through an 8 mm x 180 cm glass helix attached to a gas buret. The total pressure of solute gas plus solvent vapor is maintained at 1 atm as the gas is absorbed.		SOURCE AND PURITY OF MATERIALS: 1. Krypton. Linde Air Products Co. 2. 1,4-Dimethylbenzene. Eastman Kodak white label. Distilled. 3. 1,4-Dibromobenzene. Eastman Kodak white label. Recrystallized twice and dried in air.																			
APPARATUS/PROCEDURE: The apparatus is a modification of the apparatus of Morrison and Billett (1). The modifications include the addition of a helical storage for the solvent, a manometer for a reference pressure, and an extra buret for highly soluble gases. The solvent is degassed by a modification of the method of Baldwin and Daniel (2).		ESTIMATED ERROR: $\delta T/K = 0.05$ $\delta P/mmHg = 3$ $\delta X_1/X_1 = 0.03$

Solubility values were adjusted to a partial pressure of krypton of 101.325 kPa (1 atm) by Henry's law. Bunsen coefficients were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solvent was degassed by evacuating the space above it, shaking, and then passing it as a fine mist into another evacuated container. The degassed liquid was saturated as it passed as a thin film inside a glass helix which contained the solute gas plus solvent vapor at a total pressure of 1 atm (1,2). The volume of liquid and the volume of gas absorbed are determined in a system of burets.		1. Krypton. Linde Air Products Co. 2. Iodobenzene. Eastman Kodak white label. Shaken with aq. Na ₂ S ₂ O ₃ , dried over P ₄ O ₁₀ , distilled. b.p. 77.40 - 77.60°C (20 mmHg).

The author reports Ostwald coefficients measured at about 700 mmHg. The Bunsen coefficient and the mole fraction solubility at 101.325 kPa (1 atm) were calculated by the compiler with the assumptions that the gas is ideal, that Henry's law is obeyed, and that the Ostwald coefficient is independent of pressure.			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
Gas absorption. The method was essentially that employed by Eucken and Herzberg (1). Modifications included a magnetic stirring device instead of shaking the saturation vessel, and balancing the gas pressure against a column of mercury with electrical contacts instead of balancing the gas pressure against the atmosphere.		1. Krypton. Air Reduction Co. Reagent grade, 99.8 per cent pure by mass spectroscopy. 2. Nitromethane. Source not given. Distilled, dried by filtering at 253 K.	
APPARATUS/PROCEDURE: The solvent was degassed by vacuum. The procedure, repeated 5-10 times, was to alternate 5-15 s evacuation and rapid stirring to produce cavitation. In the solubility measurement, gas, pre-saturated with solvent vapor, was brought into contact with about 80 ml of solvent in the saturation vessel. Initial conditions were established by a time extrapolation. Solubility equilibrium was approached from both under- and supersaturation by varying the rate. AUXILIARY INFORMATION			
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus is based on the design of Morrison and Billett (1), and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus and procedure are described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing the solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		1. Krypton. Matheson Co., Inc. Minimum per cent purity 99.995. 2. Octamethylcyclotetrasiloxane. General Electric Co. Distilled density of 298.15 K was 0.9500 g cm ⁻³ .

August 1978

CRITICAL EVALUATION:

The solubility of krypton in olive oil was measured by Lawrence, Loomis, Tobias and Turpin (1) at 295.15 and 310.15 K, by Yeh and Peterson (2) at 298.15, 303.15, 310.15 and 318.15 K, and at 310.15 K by Masson and Taylor (3) and by Kitani (4).

The data were converted to a mole fraction solubility at a partial pressure of krypton of 101.325 kPa (1 atm) assuming that olive oil is 1,2,3-propanetriyl ester of Z-9-octadecenoic acid, or triolein, of molecular weight 885.46. The data from the four laboratories shows considerable scatter. Yeh and Peterson made direct volumetric measurements at atmospheric pressure while the other workers used radiochemical techniques at low krypton partial pressures in the presence of air which can be subject to greater errors than the volumetric method. The data of Yeh and Peterson are internally self-consistent. It was decided to accept the Yeh and Peterson data as the basis of a tentative set of solubility data for krypton in olive oil.

The Yeh and Peterson data were used in a linear regression of a Gibbs energy equation linear in temperature. The tentative values of the thermodynamic changes for the transfer of one mole of krypton from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are

$$\Delta G^{\circ}/J \text{ mol}^{-1} = -RT \ln X_1 = -4,690.4 + 48.782 T$$

$$\text{Std. Dev.} = 5.4, \text{ Coef. Corr.} = 0.9999$$

$$\Delta H^{\circ}/J \text{ mol}^{-1} = -4,690.4, \Delta S^{\circ}/J \text{ K}^{-1} \text{ mol}^{-1} = -48.782$$

A table of tentative mole fraction solubility and Gibbs energy values as a function of temperature appears below.

TABLE 1. The solubility of krypton in olive oil. The tentative values of the mole fraction solubility at a krypton partial pressure of 101.325 kPa (1 atm) and the Gibbs energy change as a function of temperature.

T/K	Mol Fraction $X_1 \times 10^2$	$\Delta G^{\circ}/J \text{ mol}^{-1}$
293.15	1.94	9,610.0
295.15	1.91	9,707.6
298.15	1.88	9,854.0
303.15	1.82	10,098

CRITICAL EVALUATION:

Figure 1 shows the per cent deviation of all of the reported mole fraction solubility data from the smoothed data of Yeh and Peterson. Since olive oil is a natural product that may vary somewhat in composition and thus show variation in its solvent capacity, the data sheets on all the workers are included.

FIGURE 1. Solubility of krypton in olive oil. Percent deviation from regression equation fitted to data of Yeh and Peterson.

The Bunsen coefficients are the average of three measurements. The Ostwald coefficients were fitted by the method of least squares to the equation $\log L = A/T + B$ by the authors. The same line fitted olive oil and the fats. From the slope and intercept they obtained			
$\Delta H^\circ = (-1185 \pm 46) \text{ cal mol}^{-1}$ and $\Delta S^\circ = (-5.6 \pm 0.1) \text{ cal K}^{-1} \text{ mol}^{-1}$			
The thermodynamic values are for the standard state transfer of one mole of krypton from the gas phase at a concentration of one mole dm^{-3} to the solution at a concentration of one mole dm^{-3} . See the evaluation of the krypton + olive oil system on pages 108-109 for the thermodynamic values of the standard state transfer on one mole of krypton from the gas phase at a partial pressure of one atm to the hypothetical unit mole fraction solution.			
AUXILIARY INFORMATION			
METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Oil was dried and degassed by stirring under vacuum at 80°C for about 12 hr. A 50 ml. sample was placed in an absorption flask attached to a Geffken gas buret (1). The oil was constantly stirred and equilibrated with increments of gas until no change was observed in a differential oil manometer for ½ hr. Difference between initial and final buret readings indicated amount of gas absorbed. Absorption at successively lower temperatures was determined. The authors also measured the viscosity and surface tension of the liquid.		1. Krypton. Matheson Co., Research grade, maximum impurity 0.04 mole per cent N ₂ and Xe. 2. Olive Oil. <p>CRITICAL EVALUATION:</p> <p>The solubility of krypton in biological fluids and tissues.</p> <p>There are several factors that make it difficult to compare and evaluate the solubility of krypton in biological systems. First, the material from biological specimens may show a natural variation in properties which affects the solubility. Second, workers have used quite different experimental techniques to measure the solubility. Some have used classical volumetric methods with the krypton at a partial pressure near atmospheric pressure, many have used radiochemical techniques either with natural krypton tagged with radioactive krypton at a total pressure near atmospheric or with a small unknown partial pressure of radioactive krypton. In neither of the radiochemical techniques is it necessary to know the total pressure to obtain an Ostwald coefficient. However, to compare the results of krypton solubility determinations by the volumetric method and by the radiochemical techniques one must assume the Ostwald coefficient is independent of pressure. This may not be true, especially if the gas associates with one or more components of the biological fluid. In these systems the solubility data are classed as tentative. Below are comments, which compare rather than evaluate, the solubility data in several types of biological systems.</p> <p>Fat. Yeh and Peterson (1) found little difference in the solubility of krypton in olive oil, human fat, dog fat and rat fat by a volumetric method. Masson and Taylor (2) used a radiochemical method and obtained solubility values that were eight per cent higher in olive oil and three per cent higher in human fat than Yeh and Peterson's results. The Masson and Taylor method, although elegant, appears to be more subject to error than the Yeh and Peterson technique. The results of the two laboratories probably agree within experimental error. Kirk, Parrish and Morken's (3) results with guinea pig fat are reported on a weight basis. They appear to be of similar magnitude to the solubility found in other fats.</p> <p>Blood and blood components. Several studies showed that the solubility of krypton and other gases varies linearly with the percent of either red blood cells, serum albumin, or hemoglobin in blood and in other fluids. The results of these studies are sometimes extrapolated to 100% blood component to obtain the solubility of the gas in that component. Both Hardewig, Rochester and Briscoe (4) and Kitani (5) report a value of the Ostwald coefficient of krypton in human red blood cells. The values agree within 5 per cent. Yeh and Peterson (1) show that 0.075 mole of krypton associates with a mole of human hemoglobin and that 0.2 to 0.05 mole of krypton associate with a mole of human serum albumin at temperatures of 298.15 and 310.15 K respectively. Muehlbaeher, DeBon and Featherstone (6) carried out qualitative experiments that showed that bovine hemoglobin associates with krypton while bovine gamma-globulin and serum albumin apparently do not associate. Kirk, Parrish and Morken (3) reported the solubility of krypton in dog, cat, hamster and guinea pig blood and Strang (7) reported the solubility of krypton in rabbit blood.</p> <p>Tissues. The distribution of krypton between the gas phase and the tissue can be measured either with homogenized tissue in a saline or other solution, with solid tissue, or with tissue from an animal sacrificed after breathing air containing krypton. It is likely that the structured tissue interacts somewhat differently with the gas than does the homogenized tissue, but there is not enough data to draw any conclusions about the effect of tissue structure and "solubility". Both Yeh and Peterson (1) and Strang (7) reported on work with rabbit tissues. Kitani (5) reported results with human liver tissues. Kirk, Parrish and Morken (3) reported on a range of guinea pig tissues and guinea pig brain and Yeh and Peterson (1) reported results on beef brain tissues.</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Krypton; Kr; 7439-90-9 2. Biological Systems 	<p>EVALUATOR:</p> <p>H. L. Clever Chemistry Department Emory University Atlanta, GA 30322 U.S.A.</p> <p>September 1978</p>
<p>CRITICAL EVALUATION:</p> <p>In addition there are whole blood tissue coefficients for the partition of krypton between blood and tissue determined incidental to regional blood flow studies. These results could be converted into gas-tissue coefficients using the gas-blood Ostwald coefficients. The tissue-blood partition coefficients for krypton are not given in this compilation. Many are summarized by Kirk, Parrish and Morken (3) from the work of Lassen and Munck (8), Lassen and Ingvar (9), Lassen (10, 11), Ingvar and Lassen (12), Glass and Harper (13), Thornburn, Kopald, Herd, Hollenberg, O'Morchoe, and Barger (14), Friedman, Kopald and Smith (15), Bell and Harper (16), Hollenberg and Dougherty (17), Setchell, Waites and Thorburn (18), and Bell and Battersby (19).</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. The Bunsen coefficients are the average of three measurements. The Ostwald coefficients were fitted by the method of least squares to the equation $\log L = A/T + B$ by the authors. The same line fitted olive oil and the fats. From the slope and intercept they obtained					
$\Delta H^{\circ} = (-1185 \pm 46) \text{ cal mol}^{-1}$ and $\Delta S^{\circ} = (-5.6 \pm 0.1) \text{ cal K}^{-1} \text{ mol}^{-1}$					
The thermodynamic values are for the transfer of one mole of krypton from the gas phase at a concentration of one mole dm^{-3} to the solution at a concentration of one mole dm^{-3} .					
AUXILIARY INFORMATION					
METHOD /APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
Fat was dried and degassed by stirring under vacuum at 80°C for about 12 hr. A 50 ml. sample was placed in an absorption flask attached to a Geffken gas buret (1). The fat was constantly stirred and equilibrated with increments of gas until no change was observed in a differential oil manometer for $\frac{1}{2}$ hr. Difference between initial and final buret readings indicated amount of gas absorbed. Absorption at successively lower temperatures was determined. The authors also measured the viscosity and surface tension of the liquid.			1. Krypton. Matheson Co. Research grade, maximum impurity 0.04 mole per cent N_2 and Xe.		
			2. Human omental fats obtained from two deceased patients (1 and 2). Extracted with petroleum ether (b.p. 309-338 K). The ether was evaporated at 353 K under vacuum for several hours. Stored under refrigeration until use. Fat 2 appeared to have more stearine precipitate than fat 1 at 296 K.

METHOD /APPARATUS/PROCEDURE: Liquid fat was sprayed into a circulating mixture of ^{85}Kr and air. Difference between count rate in air before and after spraying equals amount absorbed by fat. Then, radioactive gas mixture was replaced by air. The spray pump was re-connected, and increase of count rate in air was compared with original decrease. Sensor was a B-sensitive thallium activated sodium iodide crystal, behind a thin (0.008 in) beryllium window.	SOURCE AND PURITY OF MATERIALS: 1. Krypton-85. Radiochemical Centre, Amersham, U.K. 2. The authors conversion of their experimental data to the Ostwald coefficient assumed that Henry's law is obeyed and the Ostwald coefficient is independent of pressure.			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
The blood was obtained by veni-puncture (cats, dogs),cardiac puncture (guinea pigs) or intraorbital sinus puncture (Chinese hamsters). The blood was mixed with a "known volume" of 10 % EDTA to prevent clotting. The samples were equilibrated with a ⁸⁵ Kr + air atmosphere for 24 hours; samples were counted in a NaI well system. The solubility coefficients were corrected for the presence of aqueous saline and EDTA solution used as diluents.		1. Krypton. No information given. The ⁸⁵ Kr + air mixture had a count of 0.9 µCi cm ⁻³ . 2. Guinea pigs. Duncan-Hartley random bred. 700-1000 g, from commercial suppliers or bred in laboratory.	
APPARATUS/PROCEDURE:		ESTIMATED ERROR:	
The authors fitted the Ostwald coefficients in Guinea pig blood to the equation log L = -4.1378 + 889.2/T (r = 0.994)		δL/L = 0.02 - 0.14

The Ostwald coefficients in 100 % human albumin were values extrapolated from the values at lower concentration by the authors. The Bunsen coefficients and the mole fraction solubilities were calculated by the compiler. The authors used an albumin molecular weight of 69,000 and a density of 1.0 to calculate the mole ratio of krypton to albumin of 0.192, 0.122, and 0.051 at 298.15, 303.15, and 310.15 K, respectively.

Note: (1) L _w is not a valid measurement in lungs because of ⁸⁵ Kr in air spaces.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The guinea pig is enclosed in monitored air with ⁸⁵ Kr for 6 hr (1); 15 min before sacrifice, ¹³¹ I-tagged albumin (2) is injected to indicate the amount of blood in the tissue. Sacrifice, necropsy, and radioactive count at ⁸⁵ Kr level and ¹³¹ I level determine the uptake of gas in the tissue.		1. Krypton. No information given. The ⁸⁵ Kr + air mixture had a count of 0.9 µCi cm ⁻³ . 2. Guinea pigs. Duncan-Hartley random bred. 700-1000 g, from commercial suppliers or bred in laboratory.		
		ESTIMATED ERROR:		
		δL/L = 0.13 (blood) - 0.89 (bone marrow)

METHOD / APPARATUS / PROCEDURE: See preceeding page.		SOURCE AND PURITY OF MATERIALS: See preceeding page.		
		ESTIMATED ERROR: See preceeding page.		
		REFERENCES: See preceeding page.		

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Krypton-85; $^{85}_{36}\text{Kr}$; 13983-27-2 2. Human Liver Tissue 	<p>ORIGINAL MEASUREMENTS:</p> <p>Kitani, K.; Winkler, K.</p> <p><u>Scand. J. Clin. Lab. Invest.</u> 1972, <u>29</u>, 173-176.</p>
<p>VARIABLES:</p> <p>T/K: 310.15</p>	<p>PREPARED BY:</p> <p>A.L. Cramer</p>
<p>EXPERIMENTAL VALUES:</p> <p>Thirty three measurements of the solubility of krypton-85 were made in liver tissue with triglyceride content varying between 1 and 20 weight per cent. One measurement was made at 50 weight percent triglyceride. The results were given in a graph. The data fitted the regression equation</p> $L = 0.04924 + (0.004072) (\text{triglyceride wt } \%)$ <p>with a regression coefficient of 0.98.</p> <p>The triglyceride weight per cent was calculated as tripalmitin. The tissue solubility was corrected for the water added to the sample. Below a liver triglyceride content of 5 per cent the standard deviation was 0.7 per cent, at higher triglyceride content the standard error increases, and reaches a value of 5 per cent at 25 per cent triglyceride.</p> <p>Tripalmitin is hexadecanoic acid, 1,2,3-propanetriyl ester; $\text{C}_{51}\text{H}_{98}\text{O}_6$; 555-44-2.</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD /APPARATUS/PROCEDURE:</p> <p>Five g of liver tissue was homogenized at 277 K for 15 m after addition of 5 cm³ of water. A glass cuvette (1 x 1 x 10 cm) was 2/3 filled with the homogenate, and closed with a rubber stopper. The space above the homogenate was evacuated and filled with air containing krypton-85. The cuvette was rotated for 2 h in a water bath at 310 K. The radioactivity in the homogenate and in the air phase were determined by a scintillation counter placed in a thermostated box at 310 K (1).</p> <p>The triglyceride was determined enzymatically in chloroform-methanol extracts.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <ol style="list-style-type: none"> 1. METHOD/APPARATUS/PROCEDURE: Brain samples were obtained and homogenized under aseptic conditions and diluted 4:1 with sterile 0.9% saline. Penicillin (200 units/ml) and streptomycin (100 μg /ml) were added as antibacterial agents. Solubility for 20% brain homogenate in normal saline was determined and Ostwald coefficient for brain was calculated from that value.	SOURCE AND PURITY OF MATERIALS: 1. Krypton. No information given. The ^{85}Kr + air mixture had a count of 0.9 $\mu\text{Ci cm}^{-3}$. 2. Guinea pigs. Duncan-Hartley random bred. 700-1000 g, from commercial suppliers or bred in laboratory. ESTIMATED ERROR: $\delta L/L = 0.36$ (brain) $\delta L/L = 0.025$ (saline) REFERENCES:												

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Xenon; Xe; 7440-63-3 2. Water; H₂O; 7732-18-5 	<p>EVALUATOR:</p> <p>Rubin Battino, Department of Chemistry, Wright State University, Dayton, Ohio, 45435 U.S.A.</p> <p>July 1978</p>
<p>CRITICAL EVALUATION:</p> <p>The experimental solubility data of three workers was considered to be of sufficient reliability to use in the smoothing equation. In the process of fitting the data to the smoothing equation any data points which differed from the smooth equation by about two standard deviations or more were rejected. The 20 points used for the final smoothing were obtained as follows (reference - number of data points used from that reference): 1-3; 2-4; 3-11; 4-1; 5-1. The fitting equation used was</p> $\ln x_1 = A + B/(T/100K) + C \ln (T/100K) + DT/100K \quad (1)$ <p>Using T/100K as the variable rather than T/K gives coefficients of approximately equal magnitude. The best fit for the 20 data points was</p> $\ln x_1 = -74.7398 + 105.210/(T/100K) + 27.4664 \ln (T/100K) \quad (2)$ <p>where x_1 is the mole fraction solubility of xenon at 101,325 Pa partial pressure of gas. The fit in $\ln x_1$ gave a standard deviation of 0.35% taken at the middle of the temperature range. Table 1 gives smoothed values of the mole fraction solubility at 101,325 Pa partial pressure of gas and the Ostwald coefficient at 5K intervals.</p> <p>Table 1 also gives the thermodynamic functions $\Delta \bar{G}_1^\circ$, $\Delta \bar{H}_1^\circ$, $\Delta \bar{S}_1^\circ$, and $\Delta \bar{C}_{P1}^\circ$ for the transfer of gas from the vapor phase at 101,325 Pa partial gas pressure to the (hypothetical) solution phase of unit mole fraction. These thermodynamic properties were calculated from the smoothing equation according to the following equations:</p> $\Delta \bar{G}_1^\circ = -RAT - 100RB - RCT \ln (T/100) - RDT^2/100 \quad (3)$ $\Delta \bar{S}_1^\circ = RA + RC \ln (T/100) + RC + 2RDT/100 \quad (4)$ $\Delta \bar{H}_1^\circ = -100RB + RCT + RDT^2/100 \quad (5)$ $\Delta \bar{C}_{P1}^\circ = RC + 2RDT/100 \quad (6)$ <p>The results from five other laboratories were rejected for several reasons. Antropoff's data (6) were very high - being off by as much as 40%. On the other hand, König's data (7) were consistently low by 8 to 22 per cent. Steinberg and Manowitz (8) only crudely measured the solubility and their single value was 6% high. Eucken and Hertzberg's two measurements (9) were both very high (5 to 30%). Wood and Caputi's measurements (10) ranged from 12% high to 3% low although their stated precision was 0.5%.</p> <p>Figure 1 shows the temperature dependence of the solubility of xenon in water. The curve was obtained from the smoothing equation. There is no minimum in the range of the measurements, but the solubility curve flattens out markedly at the higher temperatures. The $\ln X$ equation minimum is 383 K.</p> <p>Alexander (11) made five calorimetric determinations of the xenon enthalpy of solution in water at 298.15 K. He obtained an enthalpy of solution of $-17.2 \pm 0.5 \text{ kJ mol}^{-1}$ which is 11% below the value derived from the temperature coefficient of the solubility values. We have found no reports of the partial molal volume of xenon in water.</p> <p>Ewing and Ionescu (12) determined Henry's constant of xenon in water at three temperatures. Their value at 288.15 K agrees with the recommended value, but their values at 278.15 and 298.15 K are 11.5 and 5 per cent high, respectively.</p>	

COMPONENTS:

1. Xenon; Xe; 7440-63-3
2. Water; H₂O; 7732-18-5

The mole fraction solubility at a partial pressure of xenon of 101.325 kPa was calculated by the compiler.			
The solubility, S_o , is the cm ³ xenon at 273.15 K and 101.325 kPa per kg of water at a partial gas pressure of 101.325 kPa.			
*Solubility values which were used in the final smoothing equation for the recommended solubility values given in the critical evaluation.			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
Flowing the previously degassed liquid in a thin film through the gas in an absorption spiral. Volume changes are measured in burets. See ref. 1.		1. Xenon-British Oxygen Company, Ltd. Contained about 1% krypton.

AUXILIARY INFORMATION													
METHOD: Deionized water was introduced into the reaction vessel, degassed, and then equilibrated with xenon at the desired temperature. Equilibration required up to five hours. The change in pressure of the xenon gas was measured. The moles of xenon absorbed by the water was calculated from the ideal gas equation from the pressure decrease, the gas volume and the temperature. Measurements were made at several pressures up to five atm, and the Henry's law slope determined.	SOURCE AND PURITY OF MATERIALS: 1. Xenon. J.T.Baker Chemical Co. Stated to contain the impurities Kr 10 ppm, N ₂ 50 ppm, O ₂ 5 ppm, H ₂ 5 ppm, hydrocarbons 15 ppm, and moisture 5 ppm. 2. Water. Deionized.

The mole fraction solubility at 101.325 kPa (1 atm) partial pressure of xenon was calculated by the compiler.			
*Solubility values which were used in the final smoothing equation for the recommended solubility values given in the critical evaluation.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Gas-free water and the pure gas are equilibrated, and volumetric samples of the liquid and gaseous phases are isolated. The gas dissolved in the water is extracted and the number of moles determined on a special mercury manometer. After removal of the water vapor, the number of moles in the sample of the gaseous phase is measured with the same manometer; from which the pressure (and fugacity) above the solution may be calculated. Real gas corrections are made. Predicted maximum error is 0.02%. No drawings of the apparatus are given in the original paper.		1. Xenon. No comment by authors.	
		2. Water. No comment by authors.	
		ESTIMATED ERROR:	
		Smoothed data were fit to 0.20% rms by the authors. Calculated error in the measurements was 0.02%.

CRITICAL EVALUATION:

The solubility of xenon in aqueous electrolyte solutions.

There are data on the solubility of xenon in aqueous NaCl, KI, and Na₃PO₄ solutions. The Setschenow salt effect parameters $k_s = (1/m) \log(S^0/S)$ and $k_{sx} = (1/m) \log(X^0/X)$, where S is volume of gas at STP dissolved kg⁻¹ water and X is the gas mole fraction, are summarized in Table 1.

TABLE 1. Setschenow salt effect parameters for xenon dissolved in aqueous electrolyte solution.

Electrolyte	T/K	mol salt kg ⁻¹ H ₂ O	k_s	k_{sx}	Ref.
NaCl	273.15	0.76	0.182	0.197	2
		1.17	0.185	0.200	2
		2.68	0.175	0.190	2
	293.15	0.285	0.161	0.176	2
		1.32	0.161	0.176	2
		1.80	0.154	0.169	2
	298.15	0.155	0.237	0.252	3
		1.0	0.149	0.164	1
	303.15	0.155	0.172	0.187	3
	310.15	0.155	0.143	0.158	3
	318.15	0.155	0.185	0.200	3
Na ₃ PO ₄ *	298.15	0.066	0.499	--	3
	303.15	0.066	0.462	--	3
	310.15	0.066	0.368	--	3
	318.15	0.066	0.453	--	3
KI	298.15	1.0	0.113	0.128	1

*Buffer solution, 0.066 mol Na₃PO₄ dm⁻³ solution. The Setschenow parameter is $k_L = (1/m) \log(L^0/L)$.

The Setschenow parameters from the data of Eucken and Hertzberg (2) and of Morrisson and Johnstone (1) appear to form a self-consistent set of values for aqueous NaCl solutions and they are recommended. The Setschenow salt effect parameters for aqueous NaCl solutions calculated from the data of Yeh and Peterson (3) appear high and erratic. This is partly due to the experimental difficulties in making accurate gas solubility measurements in water and dilute aqueous salt solutions and it may indicate the salt effect parameter is of greater magnitude in the dilute NaCl solution (0.155 molal) than in solutions of 1.0 molal and greater concentration. The Setschenow parameters for xenon in aqueous Na₃PO₄ solution and aqueous KI solution are tentative.

Ladefoged and Anderson (4) report the solubility of xenon-133 in water and standard saline solution. The k_s value calculated from their data is 0.188 at 310.15 K. Isbister, Schofield and Torrance (5) report the solubility of xenon-133 in saline solution. The saline solution was not defined. The solubility value appears to be high and is not recommended.

The values of the Setschenow salt effect parameter, k_s , were apparently determined from only two solubility measurements. They were the solubility of xenon in pure water, S^O , and the solubility of xenon in a near one equivalent of salt per kg of water solution, S . No solubility values are given in the paper. The S^O/S ratio was referenced to a solution containing one kg of water. The compiler calculated the salt effect parameter k_{sX} from the mole fraction solubility ratio X^O/X . The electrolytes were assumed to be 100 per cent dissociated and both cation and anion were used in the mole fraction calculation.

AUXILIARY INFORMATION																																	
METHOD / APPARATUS / PROCEDURE: Gas absorption. The apparatus consists of a gas buret and an adsorption flask connected by a capillary tube. The whole apparatus is shaken. The capillary tube is a 2m-long glass helix. An amount of gas is measured at STP and placed in the gas buret. After shaking, the difference from the original amount of gas placed in the gas buret is determined.		SOURCE AND PURITY OF MATERIALS: Components. No information given.																															
		ESTIMATED ERROR: $\delta L/L = 0.01$

COMPONENTS:

1. Xenon; Xe; 7440-63-3
2. Cyclohexane; C₆H₁₂; 110-82-7

EVALUATOR:

H. L. Clever
Chemistry Department
Emory University
Atlanta, GA 30322
U.S.A.

August 1978

CRITICAL EVALUATION:

Both Clever (1) and Dymond (2) measured the solubility of xenon in cyclohexane at four temperatures in the room temperature range. Dymond's data is more self-consistent than Clever's data. The smoothed data differs by 5.4 per cent at 288.15 K and 2.1 per cent at 308.15 K with Dymond's mole fraction solubilities greater than Clever's.

Dymond's four values and Clever's values at 307.60 and 316.25 K were combined in a linear regression of a Gibbs energy equation linear in temperature to obtain the recommended equation.

The recommended thermodynamic values for the transfer of xenon from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are

$$\Delta G^{\circ}/J \text{ mol}^{-1} = -RT \ln X_1 = -9,980.4 + 65.625 T$$

$$\text{Std. Dev. } \Delta G^{\circ} = 28.3, \text{ Coef. Corr.} = 0.9987$$

$$\Delta H^{\circ}/J \text{ mol}^{-1} = -9,980.4, \Delta S^{\circ}/J \text{ K}^{-1} \text{ mol}^{-1} = -65.625$$

The recommended values of the mole fraction solubility at 101.325 kPa and the Gibbs energy of solution as a function of temperature are given in Table 1.

TABLE 1. Solubility of xenon in cyclohexane. Recommended mole fraction solubility and Gibbs energy of solution as a function of temperature.

T/K	Mol Fraction $X_1 \times 10^2$	$\Delta G^{\circ}/J \text{ mol}^{-1}$
288.15	2.41	8,929.6
293.15	2.24	9,257.7
298.15	2.09	9,585.9
303.15	1.96	9,914.0
308.15	1.84	10,242
313.15	1.73	10,570
318.15	1.62	10,898

The solubility values were adjusted to a partial pressure of xenon of 101.325 kPa (1 atm) by Henry's law.																					
The Bunsen coefficients were calculated by the compiler.																					
AUXILIARY INFORMATION																					
METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																			
The solvent was degassed by evacuating the space above it, shaking, and then passing it as a fine mist into another evacuated container. The degassed liquid was saturated as it passed as a thin film inside a glass helix which contained the solute gas plus solvent vapor at a total pressure of 1 atm (1,2). The volume of liquid and the volume of gas absorbed are determined in a system of burets.		1. Xenon. Linde Air Products Co.																			
The smoothed data above are based on only two experimental points. They should be used with caution.		2. Toluene. Mallinckrodt. Reagent grade. Shaken over conc. H ₂ SO ₄ , water washed, dried over Drierite, distilled b.p. 110.40 - 110.60°C.																			
Evaluator's Note: Steinberg, M.; Manowitz, B. Ind. Eng. Chem. 1959, 51, 47 report an Absorption coefficient of 3.17 (mole fraction 1.41 x 10 ⁻²) at 297.15 K for this system.		ESTIMATED ERROR: δT/K = 0.03 δP/torr = 1 δX ₁ /X ₁ = 0.005

The mole fraction solubility at 101.325 kPa (760 mmHg) was calculated by Henry's law by the compiler.																																													
AUXILIARY INFORMATION																																													
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																																											
The solvent was degassed by vacuum. A thin layer of alcohol, cooled to 125-175 K, was kept for 20 hours in a vacuum maintained at 10 ⁻³ mmHg. The degassed liquid was sealed under vacuum in an ampoule which was placed in the apparatus. The apparatus consisted of a manostat, a mercury compensator, and a solubility cell divided by a mercury seal. A gas pressure of 200 mmHg and the temperature were established. The foil ends of the ampoule were pierced. The gas dissolved as the liquid flowed through a series of small cups. The amount of gas dissolved was determined by the rise in mercury level in the compensator. Some measurements were made at 400 mmHg gas pressure. The results confirmed that Henry's law was obeyed.		1. Xenon. Source not given. Purity by chromatographic method was 99.85 per cent. 2. 1-Propanol. Purified and analyzed in the All-Union Sci. Res. Inst. for Single Crystals & High-Purity Substances. Purity 99.97 weight per cent.

AUXILIARY INFORMATION				
METHOD:		SOURCE AND PURITY OF MATERIALS:		
Volumetric. The apparatus (1) is a modification of that used by Morrison and Billett (2). Modifications include the addition of a spiral solvent storage tubing, a manometer for constant reference pressure, and an extra gas buret for highly soluble gases.		1. Xenon. Matheson Co., Inc. Both standard and research grades were used.		
		2. Perfluoromethylcyclohexane. du Pont FCS-326, shaken with concentrated H ₂ SO ₄ , washed, dried over Drierite and distilled. b.p. 75.95 to 76.05° at 753 mm., lit. b.p. 76.14 at 760 mm.		
APPARATUS/PROCEDURE:		ESTIMATED ERROR:		
(a) Degassing. 700 ml of solvent is shaken and evacuated while attached to a cold trap, until no bubbles are seen; solvent is then transferred through a 1 mm capillary tubing, released as a fine mist into a continuously evacuated flask. (b) Solvent is saturated with gas as it flows through 8 mm x 180 cm of tubing attached to a gas buret. Pressure is maintained at 1 atm as the gas is absorbed.		δT/K = 0.05 δP/mmHg = 3 δx ₁ /x ₁ = 0.03

298.15(?)	1.32	5.75×10^4							
The mole fraction solubility at 101.325 kPa (1 atm) was calculated by the compiler.									
Nine solubility measurements in degassed and three solubility measurements in non-degassed tetrachloromethane between 10 and 370 mmHg Xe pressure fell within experimental error of the Henry's law line. The twelve solubilities were given on a graph along with the value of Henry's Constant.									
W. L. Kay and R. A. Penneman [US AEC TID-5215 1955, 138 - 139; Chem. Abstr. 1956, 50, 16284e] used the McDaniel method to measure Ostwald coefficients of xenon in carbon tetrachloride at several temperatures. Their values are T/K/Ostwald: 301/2.4, 304/2.3 and 2.9, and 305/2.4. The values range from 0.94×10^{-2} to 1.13×10^{-2} mole fraction xenon at a pressure of 101.325 kPa. The value of Yagi and Kondo, which is higher by 15 to 30 percent, is probably a more reliable value.

The mole fraction solubility at a xenon partial pressure of 101.325 kPa (1 atm) was calculated by the compiler. The CO ₂ density values were used from reference (1).			
A smoothed data fit with thermodynamic values for the transfer of one mole of xenon from the gas at 101.325 kPa to the hypothetical unit mole fraction xenon liquid is on the next page.			
AUXILIARY INFORMATION			
METHOD: Tracer technique (2). Corrected for 5.27 day half-life attenuation. Collimated counter with equilibrated gas-liquid samples. Xenon gas was a mixture of Xenon-133 and research grade Xe. The total pressure of the system was the equilibrium pressure of liquid CO ₂ + the Xe pressure.		SOURCE AND PURITY OF MATERIALS: 1. Xenon. Cryogenic Rare Gas Labs. Ultra high purity grade. Xenon-133. The author reports Ostwald coefficients measured at about 700 mmHg. The Bunsen coefficient and the mole fraction solubility at 101.325 kPa (1 atm) were calculated by the compiler with the assumptions that the gas is ideal, that Henry's law is obeyed and that the Ostwald coefficient is independent of pressure.				
AUXILIARY INFORMATION				
METHOD:		SOURCE AND PURITY OF MATERIALS:		
Gas absorption. The method was essentially that employed by Eucken and Herzberg (1). Modifications included a magnetic stirring device instead of shaking the saturation vessel, and balancing the gas pressure against a column of mercury with electrical contacts instead of balancing the gas pressure against the atmosphere.		1. Xenon. Air Reduction Co. Reagent grade, 99.8 per cent pure by mass spectroscopy.		
		2. Nitromethane. Source not given. Distilled, dried by filtering at 253 K.		
APPARATUS/PROCEDURE: The solvent was degassed by vacuum. The procedure, repeated 5-10 times, was to alternate 5-15 s evacuation and rapid stirring to produce cavitation. In the solubility measurement, gas, pre-saturated with solvent vapor, was brought into contact with about 80 ml of solvent in the saturation vessel. Initial conditions were established by a time extrapolation. Solubility equilibrium was approached from both under- and supersaturation by varying the rate.		ESTIMATED ERROR:		
		$\delta T/K = 0.05$ $\delta P/\text{mmHg} = 0.3$ $\delta L/L = 0.03$

EXPERIMENTAL VALUES:											
<table><tr><td>T/K</td><td>Mol Fraction X₁ x 10²</td><td>Bunsen Coefficient α</td><td>Absorption Coefficient β</td></tr><tr><td>303.15</td><td>0.173</td><td>0.43</td><td>0.45</td></tr></table>				T/K	Mol Fraction X ₁ x 10 ²	Bunsen Coefficient α	Absorption Coefficient β	303.15	0.173	0.43	0.45
T/K	Mol Fraction X ₁ x 10 ²	Bunsen Coefficient α	Absorption Coefficient β								
303.15	0.173	0.43	0.45								
The authors define the Absorption coefficient as the volume of gas, corrected to 288.15 K and 101.325 kPa, absorbed under a total system pressure of 101.325 kPa per unit volume of solvent at 288.15 K.											
The mole fraction solubilities and Bunsen coefficients were calculated by the compiler.											
The solubility of xenon in benzenamine reported by von Antropoff at 303.15 K is about 9 per cent higher than the Steinberg and Manowitz value (see next page). There is not enough information to recommend one value over the other.

Solubility values were adjusted to a partial pressure of xenon of 101.325 kPa (1 atm) by Henry's law. Bunsen coefficients were calculated by the compiler.																																				
AUXILIARY INFORMATION																																				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																																		
The solvent was degassed by evacuating the space above it, shaking, and then passing it as a fine mist into another evacuated container. The degassed liquid was saturated as it passed as a thin film inside a glass helix which contained the solute gas plus solvent vapor at a total pressure of 1 atm (1,2). The volume of liquid and the volume of gas absorbed are determined in a system of burets.		1. Xenon. Linde Air Products Co.

August 1978

CRITICAL EVALUATION:

The solubility of xenon in olive oil was measured by Lawrence, Loomis, Tobias and Turpin (1) at 295.15 and 310.15 K, by Yeh and Peterson (2) at 298.15, 303.15, 310.15 and 318.15 K and at 310.15 K by Ladefoged and Anderson (3) and by Kitani (4).

The data were converted to a mole fraction solubility at a partial pressure of xenon of 101.325 kPa (1 atm) assuming that olive oil is 1,2,3-propanetriyl ester of Z-9-octadecenoic acid, or triolein, of molecular weight 885.46. The data from the four laboratories shows considerable scatter. Yeh and Peterson made direct volumetric measurements at atmospheric pressure. The other workers used radiochemical techniques at low xenon partial pressure in the presence of a carrier gas, which can be subject to greater errors than the volumetric method. The data of Yeh and Peterson are internally self-consistent. It was decided to accept the Yeh and Peterson data as tentative values of the xenon in olive oil solubility.

The Yeh and Peterson data were used in a linear regression of a Gibbs energy equation linear in temperature. The tentative values of the thermodynamic changes for the transfer of one mole of xenon from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are

$$\Delta G^{\circ}/J \text{ mol}^{-1} = -RT \ln X_1 = -8,733.3 + 50.649 T$$

$$\text{Std. Dev.} = 4.9, \text{ Coef. Corr.} = 0.9999$$

$$\Delta H^{\circ}/J \text{ mol}^{-1} = -8,773.3, \Delta S^{\circ}/J \text{ K}^{-1} \text{ mol}^{-1} = -50.649$$

A table of tentative mole fraction solubility and Gibbs energy values as a function of temperature appears below.

TABLE 1. The solubility of xenon in olive oil. The tentative values of the mole fraction solubility at a xenon partial pressure of 101.325 kPa (1 atm) and the Gibbs energy change as a function of temperature.

CRITICAL EVALUATION:

Figure 1 shows the per cent deviation of all of the mole fraction solubility values from the smoothed data of Yeh and Peterson. Since olive oil is a natural product that may vary in composition and thus show variation in its solvent capacity it is not possible to classify any of the data as incorrect. Data sheets on all of the xenon in olive oil solubility reports are included.

FIGURE 1. Solubility of xenon in olive oil. Per cent deviation from regression line for Yeh and Peterson's data.

CRITICAL EVALUATION:

The solubility of xenon in biological fluids and tissues.

There are several factors that make it difficult to compare and evaluate the solubility of xenon in biological systems. First, the material from biological specimens may show a natural variation in properties which affects the solubility. Second, workers have used quite different experimental techniques to measure the solubility. Some have used classical volumetric methods with the xenon at a partial pressure near atmospheric pressure. Many have used radiochemical techniques either with natural xenon tagged with radioactive xenon at a total pressure near atmospheric or with a small unknown partial pressure of radioactive xenon. In neither of the radiochemical techniques is it necessary to know the total pressure to obtain an Ostwald coefficient. However, to compare the results of xenon solubility determinations by the volumetric method and by the radiochemical techniques one must assume the Ostwald coefficient is independent of pressure. This may not be true, especially if the gas associates with one or more components of the biological fluid. In these systems the solubility data are classed as tentative. Below are comments, which compare rather than evaluate, the solubility data in several types of biological systems.

Fat. Yeh and Peterson (1) found little difference between the solubility of xenon in olive oil and in human, rat, or dog fat. Conn (2) determined the distribution of xenon between water and dog fat. The distribution coefficient was converted to a gas-fat distribution coefficient on a weight basis, which if converted to a volume basis, assuming a density of 0.9 g cm^{-3} for fat, agrees with Yeh and Peterson's value.

Heme proteins. Hemoglobin and methemoglobin. Conn (2) showed that 5 to 12 weight percent solutions of human and dog hemoglobin and methemoglobin obey Henry's law at xenon partial pressures between 175 and 700 mmHg (23.33 - 93.33 kPa) at a temperature of 294.15 K. At a pressure of 700 mmHg (93.33 kPa) xenon, one mole of the protein associates with 1.9 mole of xenon, except the dog methemoglobin, which associates with 1.8 mole xenon. Schoenborn, Vogelhut and Featherstone (3) found 1.8 mole of xenon per mole of human hemoglobin at 293.15 K and a pressure of 760 mmHg (101.325 kPa). Yeh and Peterson (4) found 1.1 mole of xenon per mole of human hemoglobin at a temperature of 310.15 K and a xenon partial pressure of probably 720 mmHg (96.0 kPa). Schoenborn (5, 6) showed that Henry's law is obeyed between 0.5 and 1.5 atm (50.63 and 151.99 kPa) partial pressure xenon dissolved in a 5 per cent horse methemoglobin solution (solubility data not given) at temperatures between 273.15 and 313.15 K. Analysis of the solubility data showed about one mole of xenon bound per mole of protein at 313.15 K and nearly two moles bound at 273.15 K. The amount of xenon bound by reduced and oxyhemoglobin was the same within 5 percent as that bound by methemoglobin. X-ray diffraction analysis showed one xenon in the α sub-unit and the other in the β -sub-unit of the methemoglobin (two of each site per molecule, for a total of four sites). Wishnia (7) used a radiochemical method with xenon-133 and showed that Henry's law is not obeyed by solutions of hemoglobin in 1.8 molar $(\text{NH}_4)_2\text{SO}_4$ solution at 273.15 K (graph only). The curve was analyzed by a two step association of xenon and ferrihemoglobin.

He reported constants for the associations. Catchpool (8) reported on the solubility (graph) of xenon in a 0.5 per cent saline solution of human hemoglobin between 278.15 and 310.15 K at a xenon pressure of 1 atm (101.325 kPa). From his measurements he calculated 1.67 mole of xenon per mole of hemoglobin at 293.15 K and 1 atm (101.325 kPa) partial pressure

CRITICAL EVALUATION:

xenon gas. Meuhlbaecher, DeBon, and Featherstone (9) carried out experiments at 310.15 K in phosphate buffer solutions that showed that the solubility of xenon increases in the presence of bovine hemoglobin but not in the presence of either bovine gamma-globulin or bovine serum albumin.

The experiments on human, dog, bovine and horse hemoglobin are consistent with a two site association between hemoglobin and xenon which increases as the temperature decreases. The x-ray evidence indicates there are two sites for each of the two associations.

Myoglobin, metmyoglobin, cyanometmyoglobin. Schoenborn, Watson and Kendrew (10) equilibrated sperm whale metmyoglobin crystals with xenon at 2.5 atm (253.3 kPa) for 12 h. X-ray diffractions of the equilibrated crystal and normal material, analyzed by the difference Fourier method, showed that the xenon atom is bound to one specific site which is buried in the interior of the molecule. The xenon atom is nearly equidistant from the heme-linked histidine and a pyrrole ring of the heme group. Schoenborn and Nobbs (11) showed that the deoxymyoglobin crystal under similar conditions binds xenon to one specific site. Maestas and Ewing (12) showed that solutions of horse metmyoglobin do not obey Henry's law (graph) at 273.15 K and xenon partial pressures between 0.1 and 1.8 atm (10.133 - 182.385 kPa). The solubility curve was interpreted by a 1:1 association between metmyoglobin and xenon. However, Wishnia (7) interpreted his solubility measurements at 273.15 K in sperm whale myoglobin dissolved in either phosphate buffer (?) or 2 mol dm⁻³ (NH₄)₂SO₄ by a two step association. Ewing and Maestas (13) measured the solubility of xenon in 10 per cent horse heart myoglobin, metmyoglobin and cyanometmyoglobin between xenon partial pressures of 0.5 to 5 atm (50.63 - 506.6 kPa) at temperatures of 293.15, 298.15, and 303.15 K. The solubility (data not given) did not obey Henry's law. The solubility data were interpreted as by a single association for the xenon-cyanometmyoglobin and a two step association for the xenon-myoglobin and xenon-metmyoglobin associations. Keys and Lumry (14) report experiments that show the binding of oxygen and xenon by sperm whale myoglobin are independent up to pressures of 2 atm (202.65 kPa) xenon, but that CO and xenon binding are not independent. The evidence of one site in the crystalline material and two sites in the material in solution for xenon may be explained either by differences in configuration of the material or by a difference in accessibility of the site in the crystal and in aqueous solution.

Leghemoglobin. Leghemoglobin is a respiratory pigment found in the root nodules of most leguminous plants. Ewing and Ionescu (15) measured the solubility of xenon in 4-10 weight per cent solutions of the ferri- and ferro-leghemoglobin at 278.15, 288.15 and 298.15 K. The results (no solubility data presented) indicated a weak interaction between xenon and leghemoglobin solutions. However, the amount of xenon bound to the leghemoglobin is of the same order of magnitude as the experimental error and it was impossible to determine the stoichiometry of the interaction.

Brain Matter. Conn (2) reported water/tissue distribution coefficients for dog gray and white brain matter. Yeh and Peterson (16) reported xenon solubility in a total beef brain homogenate. Both Isbister, Schofield and Torrance (17) and Veall and Mallett (18) report xenon solubility in human gray and white matter homogenate. The solubility coefficient of xenon in human white brain matter from the two laboratories (17, 18) agrees within one per cent. The solubility of xenon in gray brain matter is approximately half the value in white matter and the agreement of the two laboratories is 20 per cent, which is outside the standard error range of the two measurements. Conn's values for dog gray and white matter, when converted to a xenon gas/tissue ratio are much higher than the values for human brain matter. Conn used the solid tissue rather than a homogenate, and he froze the tissue in liquid nitrogen before counting the absorbed radioactive xenon. The difference in the experimental techniques makes a comparison of the results of uncertain value.

CRITICAL EVALUATION:

Albumin. Conn (2) found 1.1 mole xenon per mole of human albumin at 294 K and 700 mmHg (93.33 kPa) xenon pressure. Yeh and Peterson (16) measured the solubility of xenon in three concentrations of albumin at 1 atm (101.325 kPa) and temperatures of 298.15, 303.15, and 310.15 K. These results give 0.78, 0.56 and 0.46 mole xenon per mole of albumin at 101.325 kPa and temperatures of 298.15, 303.15 and 310.15 K respectively. Ladefoged and Anderson (19) made one set of measurements at 310.15 K which appears to agree with the Yeh and Peterson value at 310.15 K.

Blood and blood components. The solubility of xenon in dog blood was studied by Conn (2). The solubility of xenon in human blood and blood components was studied by Yeh and Peterson (16), Anderson and Ladefoged (20), Ladefoged and Anderson (19), Isbister, Schofield and Torrance (17), Veall and Mallett (18) and Kitani (21). The data of Isbister *et al.*, Veall and Mallett, and Kitani agree within a 3.5 per cent range for the distribution of xenon between the gas phase and red blood cells.

Tissues. Conn (2) studied dog tissues, Yeh and Peterson (16) studied rabbit leg muscle and Kitani and Winkler (21) studied human liver tissue of varying triglyceride content. Conn's results were for the solid tissue/water distribution, and they were converted to a tissue/gas distribution by us. Conn's 'solubility' values appear to be higher than the values determined by study of tissue homogenates.

*Calculated by the compiler. cm ³ xenon at 1 atm and 294.15 K g ⁻¹ tissue.																																							
**cm ³ Xe 1 atm and 294 K/g water. Calculated from data in critical evaluation of xenon in water.																																							
AUXILIARY INFORMATION																																							
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																																					
A one ml aliquot of each solution was placed in a 100 ml glass tonometer and equilibrated with the gas mixture for 2 hours at 294 K. Three-tenths ml of each sample was withdrawn anaerobically into a 1-ml syringe and the radioactivity was determined in a scintillation counter. Water under the same partial pressure xenon was counted for the tissue/water ratio.		1. Xenon. Air Reduction Sales. Specially purified. The gas was subjected to neutron bombardment in a nuclear reactor. Resultant xenon isotopes were mainly ¹³³ Xe and ¹³⁵ Xe.																																					
Some of the hemoglobin methemoglobin and albumin systems were determined by this method.		2. Dog Blood and Components.

*calculated from experiments done at a xenon partial pressure of 700 mmHg.																																															
The solubility coefficient, S, was calculated by the compiler by multiplying the protein/water ratio by 0.118, which is the solubility coefficient of xenon g ⁻¹ water at 294.15 K (See the critical evaluation of the solubility of xenon in water.)																																															
The hemoglobin and methemoglobin solutions were 5 to 12 weight percent.																																															
The xenon gas uptake by human and dog hemoglobin and methemoglobin obeys Henry's law.																																															
AUXILIARY INFORMATION																																															
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																																													
Blood was drawn and centrifuged. The red blood cells were washed repeatedly with saline to remove serum fats. Hemoglobin was obtained by hemolysing the red blood cells with distilled water, and precipitating stroma by centrifugation. The mid-portion of the supernatant fluid was withdrawn for testing and use. Only one peak was present in a starch block electrophoresis.		1. Xenon. Air Reduction Sales. Specially purified. The gas was subjected to neutron bombardment in a nuclear reactor. Resultant xenon isotopes were mainly ¹³³ Xe and ¹³⁵ Xe.																																													
Methemoglobin was obtained by oxidizing hemoglobin with excess potassium ferricyanide or sodium nitrite.		2. Albumin. Pentex Corp. Crystalline. albumin, 2-4% g. Hemoglobin, methemoglobin. See procedure.																																													
One ml samples were drawn into a 5 ml syringe and filled with gas with a xenon partial pressure of 175 to 700 mmHg. The syringes were shaken 1-2 hours at 294 K. The gas phase was completely expelled and the solution radioactivity was determined in a scintillation counter. Water samples at the same xenon partial pressure were used to calculate the water/protein solubility ratio.		ESTIMATED ERROR: See standard error of mean above.

METHOD / APPARATUS / PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Blood from volunteer donors was heparinized and centrifuged 30 minutes at 1500 G. Samples were placed in small test tubes together with a sample of water in an air tight box containing 0.5 to 2 µCi xenon-133 in 100 ml of either air, nitrogen or oxygen. The system was stirred continuously at 310 K for 24 hours. After equilibration the samples were transferred into syringes, about 0.1 ml samples were counted in a scintillation counter and compared with water value. Authors calculated the Ostwald solubility coefficient in blood of 30, 40 and 50 percent hematocrit as 0.119, 0.129, and 0.139 respectively from the above values.		1. Xenon-133. Radiochemical Centre, Amersham, U.K. Two per cent impurity of ¹³¹ Xe and ⁸⁵ Kr. Xenon. Dansk Ilt og Briut. 99.95 mol per cent. 2. Blood components. Volunteer donors.

The Ostwald coefficients in 100 % human albumin were values extrapolated from the values at lower concentration by the authors. The Bunsen coefficients and mole fraction solubilities were calculated by the compiler. The authors used an albumin molecular weight of 69,000 and a density of 1.0 to calculate mole ratios of xenon to albumin of 0.732, 0.557, and 0.460 at the temperatures 298.15, 303.15, and 310.15 K respectively.

The xenon solubility in the myoglobin solutions did not obey Henry's law. The xenon solubility data are presented graphically in the original paper.

AUXILIARY INFORMATION

METHOD / APPARATUS / PROCEDURE: Manometric method. The amount of xenon absorbed by the solution was determined by measuring the initial pressure and the final pressure to obtain the pressure change, ΔP , and applying the ideal gas law $\Delta n = \frac{(\Delta P)V}{RT}$ To determine the amount of xenon absorbed by the hemoprotein, the amount of xenon calculated to dissolve in water at the temperature and equilibrium pressure of the experiment was subtracted from Δn . This quantity divided by the number of moles of myoglobin in the ~ 10 weight per cent solution (usually $\sim 10^{-4}$ mol) yielded the amount of xenon dissolved per mole of myoglobin. The xenon adsorptions in the hemoprotein solutions were presented graphically. No appreciable difference was noted in the results for buffered (phosphate buffer pH 8.1) and unbuffered (pH 6.95) metmyoglobin solutions.	SOURCE AND PURITY OF MATERIALS: 1. Xenon. No information. 2. Horse heart myoglobin. Calbiochem. The myoglobin was prepared by reduction of metmyoglobin by sodium dithionite. The cyanometmyoglobin was prepared from metmyoglobin by reaction with KCN and $K_3Fe(CN)_6$ in a phosphate buffer solution.
	ESTIMATED ERROR: $\delta T/K = 0.1$ $\delta K_H/\text{mmHg} = 0.05$ (Compiler)
	The adsorptions were converted to association constants for the reactions $Hp + Xe = HpXe \quad K = m_{HpXe}/m_{Hp}m_{Xe}$ $HpXe + Xe = HpXe_2$ $K' = m_{HpXe_2}/m_{HpXe}m_{Xe}$ where m is $\text{mol kg}^{-1} \text{H}_2\text{O}$.

<p>*Calculated by compiler by multiplying tissue/water xenon ratio by 0.118 cm³ Xe at 294.15 K and 101.325 kPa (1 atm) g⁻¹ water. The multiplying factor was calculated from the data in the critical evaluation of xenon in water.</p>			
AUXILIARY INFORMATION			
METHOD /APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Sample tissues weighing less than 100 mg and 1 mm or less in thickness were placed in individual cuvettes. They were equilibrated with a radioxenon-air mixture varying from 7 to 65 mmHg in several experiments. The tissues were allowed to equilibrate with the gas mixture for 1 to 8 hours. After equilibration the tissues were almost instantaneously removed from the container and plunged into a bath of liquid nitrogen. The Radioxenon concentration in the frozen samples was determined by counting the radioactivity of each in a well-type scintillation counter. The count was compared with the count in a liquid water sample equilibrated at the same xenon partial pressure.		1. Xenon. Air Reduction Sales. Specially purified. The gas was subjected to neutron bombardment in a nuclear reactor. Resultant xenon isotopes were mainly ¹³³ Xe and ¹³⁵ Xe. 2. Tissues. Taken within 10 minutes after sacrifice of the animal.

<p>EXPERIMENTAL VALUES:</p> <p>Thirty three measurements of the solubility of xenon-133 were made in liver tissue with triglyceride content varying between 1 and 20 weight per cent. One measurement was made at 50 weight percent triglyceride. The results were given in a graph. The data fitted the regression equation</p> $L = 0.09524 + (0.016447)(\text{triglyceride wt } \%)$ <p>with a regression coefficient of 0.97.</p> <p>The triglyceride weight per cent was calculated as tripalmitin. The tissue solubility was corrected for the water added to the sample. Below a liver triglyceride content of 5 per cent the standard deviation was 0.7 per cent, at higher triglyceride content the standard error increases, and reaches a value of 5 per cent at 25 per cent triglyceride.</p> <p>Tripalmitin is Hexadecanoic acid, 1,2,3-propanetriyl ester; $\text{C}_{51}\text{H}_{98}\text{O}_6$; 555-44-2.</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD /APPARATUS/PROCEDURE:</p> <p>Five g of liver tissue was homogenized at 277 K for 15 m after addition of 5 cm³ of water. A glass cuvette (1 x 1 x 10 cm) was 2/3 filled with the homogenate, and closed with a rubber stopper. The space above the homogenate was evacuated and filled with air containing xenon-133. The cuvette was rotated for 2 h in a water bath at 310 K. The radioactivity in the homogenate and in the air phase were determined by a scintillation counter placed in a thermostated box at 310 K (1).</p> <p>The triglyceride was determined enzymatically in chloroform-methanol extracts.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <ol style="list-style-type: none"> 1. METHOD /APPARATUS/PROCEDURE: Small samples of brain material were weighed, 1.0 ml of distilled water added and the mixture ground to a uniform fluid. The one ml tissue suspension was added to a sample tube, 0.1 ml of air containing about 10 μCi of Xenon-133 was added and the tube sealed. The tubes were inverted every few minutes for 2-3 hours and left overnight at 310 K. The tube was centrifuged and gas and liquid phases each counted. The solubility coefficient, S_T , is the gas tissue partition coefficient, referenced to 1 ml gas and 1 g tissue.	SOURCE AND PURITY OF MATERIALS: 1. Xenon-133. No information given. 2. Brain Matter. METHOD / APPARATUS / PROCEDURE: Know weights of grey and white matter were collected in glass containers under a known volume of saline. Fine homogenates of the material were prepared. Two ml. samples of the homogenate were introduced into the special counting tube and xenon-133 air mixture was added. Equilibration at 310 K was complete in two hours. The gas and homogenate phases were counted in a specially constructed lead collimator attached to a scintillation counter. The partition coefficient between gas and tissue was calculated from the gas homogenate partition coefficient by the formula of Kety <u>et al.</u>	SOURCE AND PURITY OF MATERIALS: 1. Xenon-133. No information given. 2. Brain material. Fresh adult human post-mortem material dissected and placed in glass container under saline solution.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Radon-222; $^{222}_{86}\text{Rn}$; 14859-67-7 2. Water; H_2O; 7732-18-5 	<p>EVALUATOR:</p> <p>Rubin Battino Department of Chemistry Wright State University Dayton, Ohio, 45431 U.S.A.</p> <p>July 1978</p>
<p>CRITICAL EVALUATION:</p> <p>Radon solubilities are special because we are dealing with a naturally radioactive isotope with a half-life of 3.8 days. The usual technique for determining the solubility of radon is to equilibrate it in a carrier gas like air or nitrogen with the liquid (or solution) it is to be dissolved in. The radon partial pressure is about 10^{-4} mm Hg (ca. 0.01 Pa). The solubility is then determined by measuring the radioactivity in the equilibrated gaseous phase and liquid phase. From this the Ostwald coefficient, L, is calculated at a given temperature according to</p> $L = \frac{\text{concentration of gas per unit volume of liquid phase}}{\text{concentration of gas per unit volume of gas phase}} \quad (1)$ <p>The Ostwald coefficient is normally defined as</p> $L = \frac{\text{volume of gas at its partial pressure and } T/K}{\text{volume of solvent used to absorb the gas at } T/K} \quad (2)$ <p>These two definitions are equal if there is no volume change on mixing or negligible volume change on mixing. For the radon partial gas pressure used in the experimental measurements, the latter is certainly the case. The mole fraction solubility at 101,325 Pa is then calculated via equation 3 with $P_1 = 101,325$ Pa.</p> $x_1 = \left[\frac{R(T/K)}{V_1^0 L P_1} + 1 \right]^{-1} \quad (3)$ <p>where R is the gas constant and V_1^0 is the molar volume of the solvent at T/K. The long extrapolation from 0.01 Pa to 101,325 Pa using Henry's law is questionable. However, by making this conversion we can treat the thermodynamic functions of all of the noble gases under the same standard state conditions. Boyle (1) did carry out a test of Henry's law by varying the $\text{Rn} + \text{Air}$ pressure from 10^{-5} mm Hg to 10^{-4} mm Hg. The solubility (Ostwald Coefficient) at 14°C varied irregularly from 0.299 to 0.307 which was considered to be within experimental error.</p> <p>We used the data of three workers for smoothing. In fitting the equation those data points which differed from the smoothed curve by about two standard deviations or more were rejected and the data then re-fitted. The 40 points used for the final smoothing equation were obtained as follows (reference - number of data points used from that reference): 1-2; 2-6; 3-32. The fitting equation used was</p> $\ln x_1 = A + B/(T/100K) + C \ln (T/100K) \quad (4)$ <p>Using T/K as the variable rather than T/K gives coefficients of approximately equal magnitude. The best fit for the 40 data points was</p> $\ln x_1 = -90.5481 + 130.026/(T/100K) + 35.0047 \ln (T/100K) \quad (5)$ <p>where x_1 is the mole fraction solubility of radon at 101,325 Pa partial pressure of gas. The fit in $\ln x_1$ gave a standard deviation of 1.02% taken at the middle of the temperature range. Table 1 gives smoothed values of the mole fraction solubility at 101,325 Pa partial pressure of gas and the Ostwald coefficient at 5K intervals.</p>

^a $\Delta\bar{C}_{p1}^\circ$ was independent of temperature and has a value of $291 \text{ J K}^{-1} \text{ mol}^{-1}$.

^b $\text{cal}_{\text{th}} = 4.184 \text{ joule}$

FIGURE 1. The mole fraction solubility of radon in water at a radon partial pressure of 101.325 kPa (1 atm).

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Radon-222; $^{222}_{86}\text{Rn}$; 14859-67-7 2. Water; H_2O; 7732-18-5 	<p>EVALUATOR:</p> <p>Rubin Battino Department of Chemistry Wright State University Dayton, Ohio, 45431 U.S.A.</p> <p>July 1978</p>
<p>CRITICAL EVALUATION:</p> <p>Table 1 also gives the thermodynamic functions $\Delta\bar{G}_1^\circ$, $\Delta\bar{H}_1^\circ$, $\Delta\bar{S}_1^\circ$, and $\Delta\bar{C}_{p1}^\circ$ for the transfer of gas from the vapor phase at 101,325 Pa partial gas pressure to the (hypothetical) solution phase of unit mole fraction. These thermodynamic properties are calculated from the smoothing equation according to the following equations:</p> $\Delta\bar{G}_1^\circ = -\text{RAT} - 100\text{RB} - \text{RCT} \ln (T/100\text{K}) \quad (6)$ $\Delta\bar{S}_1^\circ = \text{RA} + \text{RC} \ln (T/100) + \text{RC} \quad (7)$ $\Delta\bar{H}_1^\circ = -100\text{RB} + \text{RCT} \quad (8)$ $\Delta\bar{C}_{p1}^\circ = \text{RC} \quad (9)$ <p>The results from three other workers was rejected for various reasons. The single point of Hofbauer's (4) was high by about 7%. Hofmann's seven values (5) were erratically high and low between 1 and 11%. Ramstedt's three measurements (6) were also high by about 2 to 4%. Although many references quote Valentiner (7), he used other people's data for his paper.</p> <p>Figure 1 shows the temperature dependence of the solubility of radon in water. The curve was obtained from the smoothing equation. There appears to be a minimum at about 363K for the Ostwald coefficient. The mole fraction solubility minimum is at 371.45 according to the fitted equation although there is no minimum evident over the temperature range of the experimental measurements.</p> <p><u>References</u></p> <ol style="list-style-type: none"> 1. 288.15	1.07	0.323	2.48
The authors reported only the ratio $L_{\text{D}_2\text{O}} / L_{\text{H}_2\text{O}}$.			
The compiler estimated the Ostwald coefficient and mole fraction. The Ostwald coefficient was obtained by multiplying the ratio times the Ostwald coefficient recommended in the critical evaluation for radon in H ₂ O. For the mole fraction calculation it was assumed that the Ostwald coefficient was independent of pressure and that the gram mole volume of radon is 22,290 cm ³ at 273.15 K and 101.325 kPa.			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
The distribution of radon between the aqueous and gas phase was measured. The vessel for the dissolution of radon was of thin-walled Plexiglass with a volume of about 100 cm ³ , divided into two portions by a 10 mm thick partition. The partition has three vertical openings. The vessel was filled with water to the partition. The upper part of the vessel contained radon + air at a low pressure. A magnetic stirrer causes the water to circulate up through two of the partition openings and back down through the center opening. It was established that gas/liquid equilibrium was reached in 20 minutes or less.		1. Radon-222. No information given. The compiler assumed Rn-222 was the isotope used since normally it is the most available.	
		2. Water. No information given.	
After equilibrium was established, the gas phases was displaced by air, and the radon activity determined. Again equilibrium was established, the gas phase was displaced by air and the radon activity was determined. The distribution coefficient was calculated from the activities and gas and liquid volumes.		ESTIMATED ERROR:

CRITICAL EVALUATION:

The solubility of radon in aqueous electrolyte solutions.

The solubility of radon in aqueous electrolyte solution was measured by Kofler (1,2) who worked with radon-222, and by Hevesy (3) who worked with radon-219. Hevesy's results on two systems were only qualitative and of doubtful value (see p.). Kofler determined the solubility of radon-222 in aqueous solutions of thirteen electrolytes. The NH₄NO₃, NaCl and Ba(NO₃)₂ solutions were extensively studied as a function of temperature and electrolyte concentration. The other solutions were studied only at a temperature of 291.15 K.

Kofler measured the solubility of radon-222 at a radon partial pressure of less than 0.1 kPa in the presence of air as a carrier gas at a pressure of about 100 kPa. Kofler reported the radon solubility, as the equivalent of an Ostwald coefficient, and the electrolyte solution density.

In order to be able to compare the radon solubilities in electrolyte solutions with the other noble gases Kofler's data was converted into a Setschenow salt effect parameter. The solution density values were converted to molalities by the aid of the density data in The International Critical Tables (4). Kofler's (5) radon in water Ostwald coefficients were fitted to the equation

ln L⁰ = -82.0146 + 126.823/(T/100) + 34.7934 ln (T/100)

to obtain L⁰ values at the various temperatures needed in the calculation.

The Setschenow salt effect parameter was calculated as

k_L = (1/m) log (L⁰/L)

where m is the mole salt kg⁻¹ water (molality),

L⁰ is the Ostwald coefficient in water, and

L is the Ostwald coefficient in the electrolyte solution of molality m.

The results of the calculation are given in Table 1.

For the other noble gases the Setschenow salt effect parameter was calculated as k_s = (1/m) log (S⁰/S) and k_{sX} = (1/m) log (X⁰/X) where S⁰/S is the gas solubility ratio with S in cm³ (STP) gas kg⁻¹ water and X⁰/X is the gas solubility ratio with X the mole fraction with respect to water and the electrolyte ions. The k_L, k_s and k_{sX} values for radon + water + sodium chloride at 291.15 K are compared below.

Mol NaCl kg ⁻¹ water	0.220	0.542	1.00	2.59	3.35	6.20
k _L	0.313	0.262	0.235	0.179	0.167	0.133
k _s	0.303	0.253	0.227	0.171	0.159	0.124
k _{sX}	0.319	0.269	0.242	0.186	0.174	0.138

The k_L and k_{sX} values are usually within 1-4 percent of each other. Thus the magnitude and trends in k_L shown in Table 1 are also representative of the k_{sX} values.

* molality greater than saturation of NaCl (?).** value at 6.20 mol salt kg^{-1} H_2O .

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Radon-222; $^{222}_{86}\text{Rn}$; 14859-67-7 2. Water; H_2O; 7732-18-5 3. Electrolyte 	<p>EVALUATOR:</p> <p>H. L. Clever Chemistry Department Emory University Atlanta, GA 30322 U.S.A.</p> <p>August 1978</p>
<p>CRITICAL EVALUATION:</p> <p>In general the magnitude of the salt effect parameter is greater for radon than the other noble gases for a given electrolyte concentration and temperature. The trends observed in the salt effect parameter in the radon + water + barium nitrate deserve special note. There is little accurate salt effect data at electrolyte concentrations below 0.1 molal. Kofler made measurements in 0.0346 and 0.0630 molal $\text{Ba}(\text{NO}_3)_2$ that give a much larger value of the salt effect parameter than the values at higher concentration of $\text{Ba}(\text{NO}_3)_2$. Such a trend is hinted in other systems but the difficulty of making accurate measurements in the dilute salt solutions has caused the effect to be doubted. The salt effect in dilute salt solutions deserves more investigation.</p> <p>REFERENCES.</p> <ol style="list-style-type: none"> 1. Kofler, M. <u>Phys. Z.</u> 1908, <u>9</u>, 6. 2. <p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Radon; ^{222}Rn; 14859-67-7 86 2. Non-aqueous Liquids 	<p>EVALUATOR:</p> <p>William Gerrard Department of Chemistry The Polytechnic of North London Holloway, London N7 8DB U. K.</p> <p>May 1977</p>
<p>CRITICAL EVALUATION: PREAMBLE</p> <p>The determination of the solubility of radon in liquids is based on a technique so different from those used for other gases that a special explanation is required. In the gaseous phase, the concentration of radon is absolutely small, the partial pressure of radon being less than 0.1 kPa at equilibrium. Furthermore, it is present in a carrier gas (nitrogen or air), the initial pressure of the carrier gas being about 100 kPa. The liquid is therefore saturated with the carrier gas at the equilibrium partial pressure of that gas. The concentration of radon in the gaseous phase, and that in the liquid phase are separately determined by the measurement of gamma-ray emission by means of an electroscope, a condenser, or a sodium iodide scintillation counter. Up to 1910, the electroscope technique was primitive, and apparently not reliable. In 1911, Boyle (1) described the procedure of holding the vessel containing one of the phases near enough to the electroscope to cause an effective ionization which could be compared with that produced by a standard amount of radium. Ramstedt (2) put the vessel into a condenser. Nussbaum and Hursh (3) however, used a sodium iodide scintillation counter.</p> <p>The primary results were presented as the equivalent of a ratio of concentrations: concentration in the liquid phase/concentration in the gaseous phase; and this ratio was called the "absorption coefficient." It was actually stated, or tacitly assumed, that Henry's law was "obeyed," and that this ratio was independent of pressure. The ratio of concentrations was assumed to be equal to the volume of radon absorbed by an equal volume of the liquid phase, i.e. in effect the Ostwald absorption coefficient; but with the implication that the partial pressure of radon was 101.325 kPa. Nussbaum and Hursh (3), for example, used nitrogen containing a concentration of radon equivalent to 1 μC per dm^3 of nitrogen. The radioactivity was assayed by counting the gamma-rays emitted by the short-lived decay products in radioactive equilibrium with radon. The ratio: (net counts per min./cm^3 of the original liquid)/(net counts per min./cm^3 of gas) was called the Ostwald solubility coefficient, and given the symbol α. It must be emphasized that this ratio is pinned to a very small partial pressure of radon.</p> <p>For the comparison of solubilities on a molecular basis, the absorption coefficients in their primary form may not be used; they must be converted into mole ratios and mole fractions. The main purpose in doing this conversion is to check the primary data by means of the reference line procedure described by Gerrard (4), and to make easier the comparison of radon solubility values with the solubility values of other gases. The following statements indicate the basis of the conversion.</p> <ol style="list-style-type: none"> 1. The Ostwald coefficient is independent of pressure. In principle this is not valid; although deviations may be neglected in certain specific examples, they may not be in others. 2. The gram-mole volume of radon is taken to be 22,290 cm^3 at 273.15/K and a pressure, p_{Rn}, of 101.325 kPa. The gram-mole volume for other temperatures is given by $22,290 \times T/273.15$ 3. The density, ρ_S, of the liquid, S, is that for the temperature of observation of the primary data. 4. The molecular weight of the liquid, S, is taken to be the simplest formula weight, e.g. $\text{C}_2\text{H}_5\text{OH}$ (46.07) and $\text{CH}_3\text{CO}_2\text{H}$ (60.05). 5. The mole ratio is given by: (absorption coefficient/gram-mole volume) $\times (M_S/\rho_S)$ where M_S is the molecular weight, and ρ_S is the density of S. The mole fraction X_{gas} obtained by (mole ratio)/(1 + mole ratio). 	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Radon; $^{222}_{86}\text{Rn}$; 14859-67-7 2. Non-aqueous Liquids 	<p>EVALUATOR:</p> <p>William Gerrard Department of Chemistry The Polytechnic of North London Holloway, London N7 8DB U. K.</p> <p>May 1977</p>
<p>CRITICAL EVALUATION:</p> <p>There are two independent operations which have to be considered in assessing the reliability of the reported data.</p> <p>(1) The determination of concentration of radon by the measurement of gamma-ray emission is for a system in equilibrium at a partial pressure, p_{Rn}, of radon less than 0.1 kPa, and with carrier gas, initially at a pressure of about 100 kPa.</p> <p>(2) The invocation of Henry's Law is a basis for accepting the concentration ratio for conditions under (1) as equal to the absorption coefficient deemed independent of pressure, and therefore the same value for $p_{\text{Rn}} = 101.325$ kPa.</p> <p>Evaluation of the primary data expressed as absorption coefficients for the very small p_{Rn} values is a matter of assessing the accuracy of the measurement of radioactivity. The measurement of temperature is accurate enough when this is specifically carried out. The pressure, p_{Rn}, is not stated, and the assumption that the absorption coefficient is independent of pressure entails a decision identified as operation (2). The evaluator has used his own reference line procedure (4) in evaluating the radon systems.</p> <p>The assessment of reliability of the primarily observed absorption coefficient (for the very small p_{Rn}) cannot lead to the same grading as that resulting from the assumption that the primary coefficient is the same at $p_{\text{Rn}} = 101.325$ kPa. In the evaluation, the assessment is based on the primary absorption coefficients for the small prevailing p_{Rn} values.</p> <p>Nevertheless, the calculated mole fraction, x_{gas}, checked by the reference line procedure of Gerrard (4), has been used as a guide to the reliability of the primary data. It must be emphasised that none of the primary measurements of radioactivity was carried out at a measured pressure, p_{Rn}.</p> <p>All the primarily observed absorption coefficients of Boyle (1), Ramstedt (2), and of Nussbaum and Hursh (3) are acceptable. The values by Hofbauer (5) are much less reliable. Lurie's (6) values tend to be much too large, and Trautenberg's (7) values are too small.</p> <p>The publications (8, 9, 10, 11) have been cited as sources of data; but they do not contain original data.</p> <p>The values given by Gabrilova (12) for petroleum oils are not admissible; because the systems were not in equilibrium. Onuma (13) reviewed the extraction of radon by organic solvents. Krestov and Nedel'ko (14) estimated solubility data for radon in 51 organic liquids from the basis of data relating to the other noble gases. They also gave estimates for solutions of the dihalogenobenzenes in xylene.</p>	<p>EVALUATION</p>

COMPONENTS:

1. Radon-222; $^{222}_{86}\text{Rn}$; 14859-67-7
2. Methylbenzene (Toluene); C_7H_8 ; 108-88-3

EVALUATOR:

William Gerrard
Department of Chemistry
The Polytechnic of North London
Holloway, London N7 8DB
U.K.

May 1977

CRITICAL EVALUATION:

The solubility of radon-222 in methylbenzene is reported by four laboratories. Hofman (1) reports radon solubilities at 194.15 and 293.15 K, Lurie (2) at 293.15 K, Boyle (3) at 287.15 K and Ramstedt (4) at 255.15, 273.15 and 291.15 K.

The Hofman value at 194.15 K should be used with caution. If the Ostwald coefficient at 194.15 K and an approximate radon pressure of 0.1 kPa has the same value at 101.325 kPa the mole fraction solubility is 0.258 at 101.325 kPa radon pressure. However, the normal boiling point of radon is 211.4 K and thus the mole fraction solubility must, in effect, be unity at 194.15 K and 101.325 kPa.

The Hofman and the Lurie Ostwald coefficients at 293.15 K agree well but appear to be too small.

The Ostwald coefficient values of Ramstedt are probably the best available, but they are classed as tentative. The Ramstedt data, smoothed by a linear regression of a Gibbs energy equation linear in temperature, are 3.3 per cent higher than the Boyle value at 287.15 K and about 8 per cent higher than the Hofman and the Lurie values at 293.15 K.

The tentative values of the thermodynamic properties of solution for the transfer of one mole of radon from the gas at 101.325 kPa to the hypothetical unit mole fraction solution are

$$\Delta G^\circ/\text{J mol}^{-1} = -RT \ln X_1 = -12,673 + 67.505 T$$

$$\text{Std. Dev. } \Delta G^\circ = 2.8, \text{ Coef. corr.} = 0.9999$$

$$\Delta H^\circ/\text{J mol}^{-1} = -12,673, \Delta S^\circ/\text{J K}^{-1} \text{ mol}^{-1} = -67.505$$

A table of tentative mole fraction solubility and Gibbs energy values as a function of temperature appears on the Ramstedt data sheet, and below.

<p>Boyle defined the coefficient of solubility, s, as $(e_1/V_1)/(e_2/V_2)$ where e_1 is emanation in volume V_1 of liquid, and e_2 is emanation in volume V_2 of gas. The partial pressure of radon is less than 0.1 kPa. The liquid is also saturated with carrier gas (air or another gas) at the prevailing pressure, originally about 101 kPa.</p> <p>The mole fraction solubility at 101.325 kPa (1 atm) was calculated by the compiler. It was assumed that the Ostwald coefficient was independent of pressure and that the gram-mole volume of radon is 22,290 cm^3 at 273.15 K and 101.325 kPa.</p>				
AUXILIARY INFORMATION				
METHOD: Radon-222 in a carrier gas (air, or other gas not specified) is shaken with a measured volume of liquid. Radioactivity is determined in the gas and liquid phases by gamma-ray electroscope.		SOURCE AND PURITY OF MATERIALS: 1. Radon-222 2. Methylbenzene (Toluene).		
APPARATUS/PROCEDURE: The sampling bulb and mixing bulb are connected by a three-way tap. For the measurement of radioactivity, the bulbs are separately placed near to the electroscope. A diagram is given by Boyle.		ESTIMATED ERROR: $\delta T/K = 0.2$ $\delta L/L = 0.03$

COMPONENTS:

1. Radon-222; $^{222}_{86}\text{Rn}$; 14859-67-7
2. Ethanol; $\text{C}_2\text{H}_6\text{O}$; 64-17-5

EVALUATOR:

H. L. Clever
Chemistry Department
Emory University
Atlanta, GA 30322
U.S.A.

August 1978

CRITICAL EVALUATION:

Four laboratories report the solubility of radon-222 in ethanol. Trautenberg (1) reports a solubility relative to water at room temperature, Boyle (2) reports an Ostwald coefficient at 287.15 K, Ramstedt (3) reports Ostwald coefficients at 255.15, 273.15 and 291.15 K, and Hofbauer (4) reports four Ostwald coefficients between 275.15 and 310.95 K.

In the experience of the evaluator both Boyle's and Ramstedt's data are usually more reliable than Hofbauer's data. For the radon + ethanol system Hofbauer's solubility values are a consistent 15.0 to 16.5 percent higher than Ramstedt's values over the temperature range of common measurement of 273.15 to 298.15 K. For this system Boyle's single value agrees better with the Hofbauer data than the Ramstedt data. Although the evidence is conflicting, the evaluator prefers the Ramstedt data.

The tentative values of the thermodynamic changes for the transfer of one mole of radon from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are the values from the Ramstedt data:

$$\Delta G^\circ/\text{J mol}^{-1} = -RT \ln X_1 = -11,900 + 75.819 T$$

$$\text{Std. Dev. } \Delta G^\circ = 12.9, \text{ Coef. Corr.} = 0.9998$$

$$\Delta H^\circ/\text{J mol}^{-1} = -11,900, \Delta S^\circ/\text{J K}^{-1} \text{ mol}^{-1} = -75.819$$

A table of tentative mole fraction solubility and Gibbs energy values as a function of temperature at 5 degree interval between 258.15 and 298.15 K appears on the radon + ethanol data sheet of Ramstedt, and below.

AUXILIARY INFORMATION																																	
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																															
The method was based on the technique of Kofler (1,2). The radon radioactivity was measured in both the liquid and gaseous phases.		1. Radon.																															
The apparatus consists of two glass bulbs connected by a tap. Each bulb carries two separate taps. Both Hofbauer and Kofler give a diagram.		2. Ethanol (Ethyl Alcohol). Purified by distillation. The density was given.																															
The author reported a coefficient of solubility, α', based on the radon concentration ratio in the liquid and gaseous phases at equilibrium by radioactivity. The coefficient of solubility is labelled an Ostwald coefficient above. It was measured at a radon partial pressure of probably less than 0.1 kPa at equilibrium. The liquid was also saturated with air as a carrier gas at an initial pressure of about 100 kPa.		ESTIMATED ERROR:

August 1978

CRITICAL EVALUATION:

Hofbauer (1) reported four values of the solubility of radon-222 in acetic acid between 290.65 and 300.25 K, and Nussbaum and Hursh (2) reported three values between 298.15 and 323.15 K. The two smoothed data sets differ by 9-10 percent over the five degree range of common measurement, with the Hofbauer data having the higher values.

The agreement between the two data sets is marginal but within reason, when one considers the 0.1 kPa pressure of the gas in the measurement and the adjustment to the 101.325 kPa pressure for the mole fraction calculation. The two data sets were combined with a weight of 1 to Hofbauer data and a weight of 2 to the Nussbaum and Hursh data in a linear regression of a Gibbs energy equation linear in temperature. The result gives the tentative values for the transfer of one mole of radon from the gas at a partial pressure of 101.325 kPa to the hypothetical unit mole fraction solution of

$$\Delta G^\circ/\text{J mol}^{-1} = -RT \ln X_1 = -12,805 + 80.750 T$$

$$\text{Std. Dev. } \Delta G^\circ = 121, \text{ Coef. corr.} = 0.9916$$

$$\Delta H^\circ/\text{J mol}^{-1} = -12,805, \Delta S^\circ/\text{J K}^{-1} \text{ mol}^{-1} = -80.750$$

The tentative solubility and Gibbs energy values as a function of temperature are in Table 1.

TABLE 1. The solubility of radon-222 in acetic acid. Tentative values of the mole fraction solubility at 101.325 kPa and the Gibbs energy changes as a function of temperature.

The author reported a coefficient of solubility, α' , based on the radon concentration ratio in the liquid and gaseous phases at equilibrium by radioactivity. The coefficient of solubility is labelled an Ostwald coefficient above. It was measured at a radon partial pressure of probably less than 0.1 kPa at equilibrium. The liquid was also saturated with air as a carrier gas at an initial pressure of about 100 kPa.																					
The mole fraction solubility was calculated by the compiler. It was assumed that the Ostwald coefficient was independent of pressure and that the gram-mole volume of radon is 22,290 cm^3 at 273.15 K and 101.325 kPa.

August 1978

CRITICAL EVALUATION:

Hofbauer (1) reported values of the radon-222 solubility in propanoic acid at temperatures of 293.85 and 302.85 K, and Nussbaum and Hursh (2) reported three values between temperatures of 298.15 and 323.15 K.

The two data sets show more scatter than the same two laboratory's results for acetic acid. It is likely that the increase in solubility shown by the Nussbaum and Hursh data between temperatures of 310.15 and 323.15 K is in error. The 323.15 K solubility value was not used in the linear regression described below.

The two data sets were combined on a one to one weight bases in a linear regression of a Gibbs energy equation linear in temperature. The result gives the tentative values for the thermodynamic changes for the transfer of one mole of radon from the gas at a partial pressure of 101.325 kPa to the hypothetical unit mole fraction solution of

$$\Delta G^\circ/\text{J mol}^{-1} = -RT \ln X_1 = -15,919 + 85.697 T$$

$$\text{Std. Dev. } \Delta G^\circ = 159.7, \text{ Coef. corr.} = 0.9661$$

$$\Delta H^\circ/\text{J mol}^{-1} = -15,919, \Delta S^\circ/\text{J K}^{-1} \text{ mol}^{-1} = -85.697$$

The tentative solubility and Gibbs energy values as a function of temperature are in Table 1.

TABLE 1. The solubility of radon-222 in propanoic acid. Tentative values of the mole fraction solubility at 101.325 kPa partial pressure radon and the Gibbs energy change as a function of temperature.

The author reported a coefficient of solubility, α' , based on the radon concentration ratio in the liquid and gaseous phases at equilibrium by radioactivity. The coefficient of solubility is labelled an Ostwald coefficient above. It was measured at a radon partial pressure of probably less than 0.1 kPa at equilibrium. The liquid was also saturated with air as a carrier gas at an initial pressure of about 100 kPa.			
The mole fraction solubility was calculated by the compiler. It was assumed that the Ostwald coefficient was independent of pressure and that the gram-mole volume of radon is 22,290 cm^3 at 273.15 and 101.325 kPa.			
Smoothed Data: $\Delta G^\circ/\text{J mol}^{-1} = -RT \ln x_1 = -7,321.1 + 56.535 T$

The Ostwald coefficient was measured at a very low partial pressure of radon. The carrier gas was nitrogen at a partial pressure of about 100 kPa. The liquid was therefore saturated with nitrogen at the experimental pressure.			
The mole fraction solubility of radon at a pressure of 101.325 kPa was calculated by the compiler. It was assumed that the Ostwald coefficient was independent of pressure and that the gram-mole volume of radon is 22,290 cm ³ at 273.15 K and 101.325 kPa.			
Smoothed Data: $\Delta G^\circ/\text{J mol}^{-1} = -RT \ln X_1 = -11,308 + 57.489 T$			
Std. Dev. $\Delta G^\circ = 34.4$, Coef. Corr. = 0.9989			
$\Delta H^\circ/\text{J mol}^{-1} = -11,308$, $\Delta S^\circ/\text{J K}^{-1} \text{ mol}^{-1} = -57.489$

CRITICAL EVALUATION:

Lurie (1) reports Ostwald coefficients for radon-222 in olive oil at temperatures of 273.15, 288.15, 313.15 and 333.15 K. Both Strasburger (2) and Schrodtt (3) report a "room temperature" Ostwald coefficient which agrees with the Lurie 288.15 K value. Nussbaum and Hursh (4) report Ostwald coefficients at 298.15 and 310.15 K which are about one-third the Lurie values, and may be taken as reliable.

The mole fraction solubility of radon-222 in olive oil was calculated assuming that olive oil is 1,2,3-propanetriyl ester of (Z)-9-octadecenoic acid, or triolein, of molecular weight 885.46. The Nussbaum and Hursh solubility values are preferred.

The tentative values of the thermodynamic properties of solution for the transfer of one mole of radon from the gas at 101.325 kPa (1 atm) to the hypothetical unit mole fraction solution are

$$\Delta G^{\circ}/J \text{ mol}^{-1} = -RT \ln X_1 = -11.914 + 51.962 T$$

$$\Delta H^{\circ}/J \text{ mol}^{-1} = -11.914, \Delta S^{\circ}/J \text{ K}^{-1} \text{ mol}^{-1} = -51.962$$

A table of tentative mole fraction solubility and Gibbs energy values as a function of temperature appears on the radon + olive oil data sheet of Nussbaum and Hursh, and in Table 1 below.

Lawrence, Loomis, Tobias and Turpin (5) cite Bunsen coefficients for radon-222 in olive oil which they attribute to Lurie and state to be given in the International Critical Tables (6). The values are 0.01 times the values reported by Lurie. They are not found in the International Critical Tables, but they are in Seidell and Linke (7) which cite no other of Lurie's data. The radon in olive oil data cited in these references (5,7) are in error and should not be used.

<p>APPARATUS/PROCEDURE:</p>	<p>ESTIMATED ERROR:</p> <p>REFERENCES:</p> <p>1. Nussbaum, E.; Hursh, J. B. <u>J. Phys. Chem.</u> 1958, <u>62</u>, 81.</p>

<p>COMPONENTS:</p> <p>1. Radon-219 (Actinium Emanation); $^{219}_{86}\text{Rn}$; 14835-02-0</p> <p>2. Liquids</p>	<p>EVALUATOR:</p> <p>William Gerrard Department of Chemistry The Polytechnic of North London Holloway, London N7 8DB United Kingdom</p>
<p>CRITICAL EVALUATION:</p> <p>The half life of radon-219 (actinon) is only 3.92 seconds. The mean values of the partition coefficient show a variation from 5 to 10 % (one is 20 %) from the observed maximum. The partition coefficient for the non-aqueous liquid, or the aqueous solution, was given as that compared with water, taken to be 2. The evaluator contends that it is much more reliable to take the observed radon-222 values as those for radon-219 (actinon).</p> <p>Hevesy's (1,2) results for the solubility of radon-219 in various liquids are on the following data sheets.</p> <p>1. Hevesy, G. <u>Phys. Z.</u> 1911, <u>12</u>, 1214.</p> <p>2. Hevesy, G. <u>J. Phys. Chem.</u> 1912, <u>16</u>, 429.</p>

Carbon Disulfide; CS_2 ; 75-15-0			
"Ordinary Temperatures:		2.1	4.2
<p>The author reported a partition coefficient of radon-219 between liquid and air relative to the partition coefficient of radon-219 between air and water, which was taken as 2. We have called the partition coefficient an Ostwald coefficient.</p> <p>The Ostwald coefficient was measured at a radon partial pressure of less than 0.1 kPa at equilibrium. The radon was present in air as a carrier gas.</p>			
AUXILIARY INFORMATION			
METHOD:		SOURCE AND PURITY OF MATERIALS:	
Dried air was passed over a radon-219 preparation, and then through a column of liquid in which part was absorbed, and the remainder passed to the ionization chamber of an electroscope.		No details.	
APPARATUS/PROCEDURE:		ESTIMATED ERROR:	
Assembly for the "dynamical flow method" as distinct from the shaking method. Radioactivity was measured. The partial pressure of radon-219 was extremely small.		$\delta L/L = 0.05 - 0.10$	
		REFERENCES:	

<p>COMPONENTS:</p> <p>1. Radon-220 (Thorium Emanation); $^{220}_{86}\text{Rn}$; 22481-88-7</p> <p>2. Liquids</p>	<p>EVALUATOR:</p> <p>William Gerrard Department of Chemistry The Polytechnic of North London Holloway, London N7 8DB United Kingdom</p>
<p>CRITICAL EVALUATION:</p> <p>The half life of radon-220 (thoron), $^{220}_{86}\text{Rn}$, is 54.5 seconds. Therefore the reported absorption coefficients must be accepted with caution. Boyle (1) used a streaming method (diagram given in the original paper) and placed the following liquids in the order of increasing solutility: but did not give actual values: CuSO_4 (aqueous) < CaCl_2 (aqueous) < water < H_2SO_4 < alcohol < petroleum; "the same as for radon (radon-222)."</p> <p>Klaus (2) reported the solubility of radon-220 in water and petroleum (see the following two data sheets).</p> <p>The evaluator contends that it is much more reliable to take the observed values for radon-222 as the values for radon-220 (thoron).</p> <p>References: 1. Boyle, R.W., <u>Le Radium</u>, 1910, <u>7</u>, 200. See also Boyle, R.W., <u>Bull. Macdonald Physics Bldg.</u>, 1910, <u>1</u>, 52.</p> <p>2. Klaus, A. <u>Phys. Z.</u> 1905, <u>6</u>, 820.</p>

SYSTEM INDEX

Underlined page numbers refer to the evaluation text and those not underlined to the compiled tables for that system. The compounds are listed in the order as in the Chemical Abstract indexes, for example toluene is listed as benzene, methyl- and dimethylsulfoxide is listed as methane, sulfinylbis-.

A

Acetate, butyl, see acetic acid, butyl ester	
ethyl, see acetic acid, ethyl ester	
Acetic acid (glacial) + krypton	84
+ radon-222	<u>291</u> , 292-293
+ xenon	171
butyl ester + krypton	85
ethyl ester + radon-222	312
pentyl ester + radon-222	313
Acetone, see 2-propanone	
Acids, see under individual acids	
Acrylic acid, see 2-propenoic acid	
Adrenals, see guinea pig adrenals	
Albumin, human, see human albumin	
Alpha-D-glucopyranoside, beta-D-fructofuranosyl-, see sucrose	
Ammonia + krypton (high pressure)	105
Ammonium chloride (aqueous) + krypton	12- 13, 14
chloride (aqueous) + radon-222	<u>238-241</u> , 242
nitrate (aqueous) + radon-222	<u>238-241</u> , 243
tetraethyl bromide, see ethanaminium, N,N,N-	
triethyl bromide	
tetramethyl iodide, see methanaminium,	
N,N,N-trimethyl iodide	
Amsco + krypton	70
+ xenon	169
Amyl acetate, see acetic acid, pentyl ester	
alcohol, see 1-pentanol	
Aniline, see benzenamine	

B

Barium chloride (aqueous) + krypton	<u>12- 13</u> , 19
nitrate, see nitric acid, barium salt	
Beef tallow + radon-222	331
Benzaldehyde + radon-219	<u>339</u> , 342
Benzenamine + radon-222	320
+ xenon	188, 189
Benzene + krypton	62
+ radon-219	<u>339</u> , 341
+ radon-222	264
+ xenon	166
bromo- + krypton	93
bromo- + xenon	179
chloro- + krypton	91
chloro- + xenon	178
1,4-dibromo- + krypton	94
1,4-dibromo-, (ternary) + krypton	94
1,2-Benzenedicarboxylic acid, dibutyl ester + krypton	85
Benzene 1,4-dichloro- + krypton	92
1,4-dichloro-, (ternary) + krypton	92
1,4-diiodo- + krypton	96
1,4-diiodo-, (ternary) + krypton	96
diphenyl-, see terphenyl	
dimethyl, + radon-222	270, 271
1,2-dimethyl- + krypton	64
1,3-dimethyl- + krypton	65
1,4-dimethyl- + krypton	66, 67
1,4-dimethyl-, (ternary) + krypton	92, 94, 96
1,4-dimethyl- + xenon	168
fluoro- + krypton	89
fluoro- + xenon	177
hexafluoro- + krypton	90
iodo- + krypton	95
iodo- + xenon	180

B

Benzene, methyl-	+ krypton	63
methyl-	+ radon-219	339, 341
methyl-	+ radon-222	265, 266 - 269
methyl-	+ xenon	167, 168, 191
methyl- (ternary)	+ xenon	191
nitro-	+ krypton	104
nitro-	+ radon-222	321
nitro-	+ xenon	190
1,3,5-trimethyl-	+ krypton	69
1,3,5-trimethyl-	+ xenon	168
Blood,	see cat blood, chinese hamster blood, dog blood, guinea pig blood, rabbit blood, human red blood cells	
Bone marrow,	see guinea pig bone marrow	
Bovine brain (saline homogenate)	+ krypton	132
brain (saline homogenate)	+ xenon	224
gamma-globulin (aqueous)	+ krypton	122
gamma-globulin (aqueous)	+ xenon	210
hemoglobin (aqueous)	+ krypton	122
hemoglobin (aqueous)	+ xenon	210
serum albumin (aqueous)	+ krypton	122
serum albumin (aqueous)	+ xenon	210
Brain matter,	see dog brain grey matter, dog brain white matter, human brain grey matter, human brain white matter	
guinea pig,	see guinea pig brain	
Bromide potassium,	see potassium bromide	
tetraethyl ammonium,	see ethanaminium, N,N,N- triethyl bromide	
Bromobenzene,	see benzene, bromo-	
Bromoform,	see methane, tribromo-	
1-Butanamine, 1,1,2,2,3,3,4,4,4-nonafluoro-N,N-bis (nonafluorobutyl)-,	+ krypton	97
1,1,2,2,3,3,4,4,4-nonafluoro-N,N-bis (nonafluorobutyl)-,	+ xenon	185
Butanoic acid	+ radon-222	299, 300
acid, 1,2,3-propanetriyl ester	+ radon-222	315
1-Butanol	+ krypton	76
1-Butanol	+ radon-222	280
2-Butanol	+ radon-222	281
1-Butanol, 3-methyl-,	+ radon-222	283
Butter fat	+ radon-222	335
Butter, cocoa,	see cocoabutter	
Butyl acetate,	see acetic acid, butyl ester	

C

Carbon dioxide (ternary)	+ krypton	98 - 99
dioxide (ternary)	+ krypton-85	98 - 99
dioxide (ternary)	+ xenon	181, 182
dioxide (ternary)	+ xenon-133	181, 182
disulfide	+ krypton	100
disulfide	+ radon-219	339, 342
disulfide	+ radon-222	319
disulfide	+ xenon	183
tetrachloride,	see methane, tetrachloro-	
Cat blood	+ krypton-85	125
Chinese hamster blood	+ krypton-85	125
Chloride, ammonium,	see ammonium chloride	
barium,	see barium chloride	
lithium,	see lithium chloride	
potassium,	see potassium chloride	
sodium,	see sodium chloride	
Chlorobenzene,	see benzene, chloro-	
Chloroform,	see methane, trichloro-	
Choroid layer, rabbit,	see rabbit choroid layer	
Cocoabutter	+ radon-222	331
Colza oil	+ radon-222	332
Copper sulfate,	see sulfuric acid, copper salt	
Cyclohexane	+ krypton	52, 53 - 54

C

Cyclohexane	+ radon-222	263
	+ xenon	<u>162</u> , 163 - 164
1,2-dimethyl-, cis-,	+ krypton	57
1,2-dimethyl-, trans-,	+ krypton	58
1,3-dimethyl-,	+ krypton	59
1,4-dimethyl-,	+ krypton	60
methyl-,	+ krypton	55
methyl-,	+ xenon	165
undecafluoro (trifluoromethyl)-, + krypton		86
undecafluoro (trifluoromethyl)-, + xenon		172
Cyclohexanol	+ krypton	82
Cyclooctane	+ krypton	56
Cyclotetrasiloxane, octamethyl-,	+ krypton	107

D

Decane	+ krypton	<u>35</u> , 40 - 42
	+ xenon	159
Decanoic acid	+ radon-222	306
1-Decanol	+ krypton	80
1,4-Dibromobenzene, see benzene, 1,4-dibromo-		
Dibutyl phthalate, see 1,2-benzene dicarboxylic acid, dibutyl ester		
1,4-Dichlorobenzene, see benzene, 1,4-dichloro-		
Diethyl ether, see ethane, 1,1-oxybis-		
1,4-diiodobenzene, see benzene, 1,4-diiodo-		
Dimethylbenzene, see benzene, dimethyl-		
1,2-Dimethylbenzene, see benzene, 1,2-dimethyl-		
1,3-Dimethylbenzene, see benzene, 1,3-dimethyl-		
1,4-Dimethylbenzene, see benzene, 1,4-dimethyl-		
1,2-Dimethyl cyclohexane, see cyclohexane, 1,2-dimethyl-		
1,3-Dimethyl cyclohexane, see cyclohexane, 1,3-dimethyl-		
1,4-Dimethyl cyclohexane, see cyclohexane, 1,4-dimethyl-		
2,3-Dimethylhexane, see hexane, 2,3-dimethyl-		
2,4-Dimethylhexane, see hexane, 2,4-dimethyl-		
Dimethyl sulfoxide, see methane, sulfinyl bis-		
Diphenylbenzene, see terphenyl		
Disulfide, carbon, see carbon disulfide		
Dodecane	+ krypton	44 - 46
	+ xenon	160
Dodecanoic acid	+ radon-222	308
Dog blood	+ krypton-85	125
	+ xenon	207
Dog brain grey matter	+ xenon	221
brain white matter	+ xenon	221
erythrocytes	+ xenon	207
fat	+ krypton	<u>114</u> , <u>115</u> , 119
fat	+ xenon	<u>199</u> , <u>204</u> , 221
hemoglobin (aqueous)	+ xenon	207, 208
methemoglobin (aqueous)	+ xenon	208
tissues	+ xenon	221
Dowtherm A	+ xenon	192
Dow Corning anti-foam A	+ xenon	192
Dow Corning silicone oil, see silicone oil		

E

EDTA, see glycine, N,N'-1,2-ethanediybis(N-carboxymethyl)-		
Electrolyte (aqueous)	+ krypton	<u>12-13</u> , 14-24, 124-125
	+ radon	<u>238-241</u> , 242-255, 340
	+ xenon	<u>149</u> , 150 - 154
Erythrocytes, rabbit, see rabbit erythrocytes		
Ethanaminium, N,N,N-triethyl-, bromide	+ krypton	<u>12 - 13</u> , 15
Ethane, 1,1-oxybis-,	+ radon-222	288
1,2-trichloro-1,2,2-trifluoro-	+ xenon	174
Ethanol	+ krypton	73, 74
	+ radon-219	<u>339</u> , 342
	+ radon-222	<u>273</u> , <u>274</u> - 277
(aqueous)	+ radon-222	256
Ethyl acetate, see acetic acid, ethyl ester		
Eucerin anhydricum	+ radon-222	331

E

Eucerin cum aqua	+ radon-222	331
Eyes, guinea pig, see guinea pig eyes		

F

Fat, butter, see butter fat		
dog, see dog fat		
human, see human fat		
rat, see rat fat		
subcutaneous, guinea pig, see guinea pig subcutaneous fat		
Ferrate(4-) hexakis (cyano-C)-, tetrapotassium (OC-9-11)- (aqueous)	+ radon-222	<u>238 - 241</u> , 253
Ferrocyanide, potassium, see ferrate (4-), hexakis (cyano-C)-tetrapotassium (OC-9-11)		
Ferrous sulfate, see sulfuric acid iron (2+) salt		
Fluorobenzene, see benzene, fluoro-		
Formic acid	+ radon-222	290
Freon 113, see ethane, 1,1,2-trichloro-1,2,2-trifluoro-		
Freon 12, see methane, dichlorodifluoro-		

G

Gasoline	+ krypton	68
Glycerol, see 1,2,3-propanetriol		
hexanoate, see hexanoic acid, 1,2,3-propanetriyl ester		
octanoate, see octanoic acid, 1,2,3-propanetriyl ester		
triacetate, see 1,2,3-propanetriol, triacetate		
tributurate, see butanoic acid, 1,2,3-propanetriyl ester		
Glycine, N,N'-1,2-ethanediybis(N-carboxymethyl)-, (aqueous)	+ krypton-85	125
Guinea pig adrenals	+ krypton-85	129
blood	+ krypton-85	125, 130
bone marrow	+ krypton-85	129
brain (in sodium chloride solution)		
brain	+ krypton-85	130
brain (in sodium chloride solution)	+ krypton-85	130
eyes (whole)	+ krypton	133
heart	+ krypton-85	130
kidneys	+ krypton-85	130
large intestine	+ krypton-85	129
liver	+ krypton-85	129
lungs	+ krypton-85	129
lymph nodes	+ krypton-85	129
muscle	+ krypton-85	130
omental fat	+ krypton-85	130
ovaries	+ krypton-85	130
seminal vesicles	+ krypton-85	130
small intestine	+ krypton-85	129
spleen	+ krypton-85	130
stomach	+ krypton-85	130
subcutaneous fat	+ krypton-85	129
testes	+ krypton-85	130
thymus	+ krypton-85	129
thyroids	+ krypton-85	129
uterus	+ krypton-85	130

H

Hamster blood, Chinese, see Chinese hamster blood		
Heart, guinea pig, see guinea pig heart		
Hemoglobin, see bovine hemoglobin, dog hemoglobin, human hemoglobin		
Heptane	+ krypton	30
	+ xenon	157
3-methyl-	+ krypton	31
Heptanoic acid	+ radon-222	303
Hexadecane	+ krypton	49

H

Hexadecane	+ xenon	161
Hexafluorobenzene, see benzene, hexafluoro-		
Hexane	+ krypton	<u>26</u> , 27 - 29
	+ radon-222	262
	+ xenon	156
2,3-dimethyl-	+ krypton	32
2,4-dimethyl-	+ krypton	33
Hexanoic acid	+ radon-222	302
acid, 1,2,3-propanetriyl ester	+ radon-222	316
Horse heart cyanometmyoglobin, metmyoglobin and myoglobin (aqueous)	+ xenon	220
Human albumin (in sodium chloride aqueous solution)		
	+ krypton	126
albumin (in sodium chloride aqueous solution)	+ xenon	208, 216, 217
blood	+ krypton	123
blood	+ radon-222	337
blood	+ xenon	211
blood	+ xenon-133	212 - 214
brain grey matter	+ xenon-133	225, 226
brain white matter	+ xenon-133	225, 226
erythrocytes	+ xenon-133	215
fat	+ krypton	<u>114-115</u> , 116 - 117
fat	+ radon-222	335
fat	+ xenon	<u>199</u> , 202
hemaglobin (aqueous)	+ krypton	123
hemaglobin (aqueous)	+ krypton-85	124
hemaglobin (aqueous)	+ xenon	<u>199 - 200</u>
		208, 209, 211
liver tissue	+ krypton-85	131
liver tissue	+ xenon-133	223
methemoglobin (aqueous)	+ xenon	<u>199 - 200</u> , 208
methemoglobin (saline)	+ xenon-133	<u>199 - 200</u> , 219
red blood cells	+ krypton-85	121
red blood cells	+ xenon-133	213, 214, 218
Hydrochloric acid	+ krypton	<u>12 - 13</u> , 16

I

Iodide, potassium, see potassium iodide		
tetramethyl ammonium, see methanaminium, N,N,N-trimethyl iodide		
Iodobenzene, see benzene, iodo-		
Isobutanol, see 1-propanol, 2-methyl-		

K

Kaiserol	+ radon-222	325
Kidneys, guinea pig, see guinea pig kidneys		
Koppers emulsion K-900	+ xenon	191

L

Lanolin	+ radon-222	331
Lard	+ radon-222	331
Large intestine, see guinea pig large intestine		
Lauric acid, see dodecanoic acid		
Lead nitrate, see nitric acid, lead salt		
Lecithin	+ krypton-85	120
	+ radon-222	338
	+ xenon-133	206
Linoleic acid, see 9,12-octadecadienoic acid		
Lithium chloride (aqueous)	+ krypton	<u>12 - 13</u> , 21
Liver, see guinea pig liver		
Lungs, see guinea pig lungs		
Lymph nodes, see guinea pig lymph nodes		

M

Mercury chloride (aqueous)	+ radon-222	<u>238 - 241</u> , 247
Mesitylene, see benzene 1,3,5-trimethyl-		
Methanaminium, N,N,N-trimethyl-, iodide	+ krypton	<u>12 - 13</u> , 15

M

Methane, dichlorodifluoro-	+ krypton	87
dichlorodifluoro-	+ xenon	173
nitro-	+ krypton	103
nitro-	+ xenon	187
sulfinylbis-	+ krypton	101
sulfinylbis-	+ xenon	184
tetrachloro-	+ krypton	88
tetrachloro-	+ xenon	176
tribromo-	+ krypton	88
trichloro-	+ krypton	88
trichloro-	+ radon-222	318
trichloro-	+ xenon	175
Methanol	+ krypton	<u>71</u> , 72
	+ radon-222	272

Methylbenzene, see benzene, methyl-
Methylcyclohexane, see cyclohexane, methyl-
3-Methylheptane, see heptane, 3-methyl-
2-Methyl propanoic acid, see propanoic acid, 2-methyl-
2-Methyl-1-propanol, see 1-propanol, 2-methyl-
Muscle, guinea pig, see guinea pig muscle
Myoglobin, see horse heart myoglobin

N

Naphthalene, 1,2,3,4-tetrahydro-	+ krypton	61
Nitrate, barium, see nitric acid, barium salt		
lead, see nitric acid, lead salt		
silver, see nitric acid, silver salt		
Nitric acid	+ krypton	12 - 13, 16
acid, potassium salt (aqueous)	+ krypton	<u>12 - 13</u> , 24
acid, barium salt (aqueous)	+ radon-222	<u>238 - 241</u> , 250
acid, lead salt (aqueous)	+ radon-222	<u>238 - 241</u> , 248
acid, silver salt (aqueous)	+ radon-222	<u>238 - 241</u> , 245
Nitrobenzene, see benzene, nitro-		
Nitromethane, see methane, nitro-		
Nitrous oxide	+ krypton	102
oxide	+ xenon	186
1,1,2,2,3,3,4,4,4-Nonafluoro-N,N-bis (nonafluorobutyl)-		
1-butanamine, see 1-butanamine, 1,1,2,2,3,3,-		
4,4,4-nonafluoro-N,N-bis (nonafluorobutyl)-		
Nonane	+ krypton	39
	+ xenon	159
Nonanoic acid	+ radon-222	305
Non-aqueous liquids	+ radon-222	<u>259 - 261</u>

O

(Z,Z)-9,12-Octadecadienoic acid	+ radon-222	310
(Z)-9-Octadecanoic acid	+ radon-222	311
Octamethylcyclotetrasiloxane, see cyclotetrasiloxane, octamethyl-		
Octane	+ krypton	<u>35</u> , 36 - 38
	+ xenon	159
Octanoic acid	+ radon-222	304
acid, 1,2,3-propanetriyl ester	+ radon-222	317
1-Octanol	+ krypton	79
Oil, see colza oil, olive oil, paraffin oil, poppy oil, silicone oil, vaseline oil		
Oleic acid, see 9-octadecenoic acid		
Olive oil	+ krypton	<u>108-109</u> , 110 - 113
oil	+ radon-222	<u>328</u> , 329 - 331
oil	+ xenon	<u>193-194</u> , 195 - 198
Omental fat, see guinea pig omental fat		
Ovaries, see guinea pig ovaries		
1,1-Oxybisethane, see ethane, 1,1-oxybis-		

P

Paraffin oil	+ krypton	68
oil	+ krypton-85	120
oil	+ radon-222	<u>322</u> , 325, 326, 331
oil	+ xenon-133	205, 206

P

Pentadecane	+ krypton	49
	+ xenon	161
Pentane	+ krypton	25
	+ xenon	155
2,2,4-trimethyl-	+ krypton	34
2,2,4-trimethyl-	+ xenon	158
Pentanoic acid	+ radon-222	301
1-Pentanol	+ krypton	78
	+ radon-222	284, 285
	+ radon-219	<u>339</u> , 342
Perfluorohexane, see benzene, hexafluoro-		
methylcyclohexane, see cyclohexane, undecafluoro-		
(trifluoromethyl)-		
tributylamine, see 1-butanamine, 1,1,2,2,3,3,4,4,4-		
nonafluoro-N,N-bis (nonafluorobutyl)-		
Permanganate, potassium, see permanganic acid, potassium salt		
Permanganic acid, potassium salt (aqueous)	+ radon-222	<u>238 - 241</u> , 254
Petroleum	+ krypton	68
	+ radon-219	<u>339</u> , 341
	+ radon-220	<u>343</u> , 345
	+ radon-222	<u>322</u> , <u>323</u> - 325
ether	+ radon-222	<u>322</u> , 325
Phosphate, tricesyl-, see phosphoric acid, tris(methylphenyl) ester		
Phosphoric acid, sodium salt (phosphate buffer in water)	+ krypton	<u>12 - 13</u> , 23
sodium salt (phosphate buffer in water)	+ xenon	<u>149</u> , 154
tris (methylphenyl) ester	+ krypton	106
Pine oil	+ xenon	191
oil (ternary)	+ xenon	191
Plasma	+ krypton-85	121, 124, 127
	+ xenon-133	207, 213 - 215
		218
Poppy oil	+ radon-222	333
Potassium bromide (aqueous)	+ krypton	<u>12 - 13</u> , 21
chloride (aqueous)	+ krypton	<u>12 - 13</u> , 21
chloride (aqueous)	+ radon-219	<u>349</u> , 340
chloride (aqueous)	+ radon-222	<u>238 - 241</u> , 255
ferrocyanide, see ferrate (4-), hexakis (cyano-C)-, tetrapotassium (OC-9-11)-		
iodide (aqueous)	+ krypton	<u>12 - 13</u> , 21
iodide (aqueous)	+ xenon	<u>149</u> , 151
nitrate, see nitric acid, potassium salt		
permanganate, see permanganic acid, potassium salt		
1,2,3-Propanetriol	+ krypton	81
	+ radon-222	286, 287
triacetate	+ radon-222	314
Propanoic acid	+ radon-222	<u>294</u> , 295 - 296
2-methyl-	+ radon-222	298
1-Propanol	+ krypton	75
	+ radon-222	278
	+ xenon	170
2-methyl-	+ krypton	77
2-methyl-	+ radon-222	282
2-Propanol	+ radon-222	279
2-Propanone	+ krypton	83
	+ radon-222	289
Propene	+ krypton (high pressure)	50, 51
2-Propenoic acid	+ radon-222	297

R

Rabbit blood	+ krypton-85	127
choroid layer	+ krypton-85	127
erythrocytes	+ krypton-85	127
leg muscle (saline homogenate)	+ krypton	128
leg muscle (saline homogenate)	+ xenon	222

R

Rabbit plasma	+ krypton-85	127
retina	+ krypton-85	127
sclera	+ krypton-85	127
vitreous body	+ krypton-85	127
Rat blood (venous)	+ radon-222	336
fatty acids (extracted)	+ radon-222	335
fat (pooled)	+ krypton	<u>114 - 115</u> , 118
fat (pooled)	+ radon-222	336
fat (pooled)	+ xenon	<u>199</u> , 203
tissues	+ radon-222	336
Retina, rabbit, see rabbit retina		

S

Saline solution, see sodium chloride (aqueous)		
Sclera, rabbit, see rabbit sclera		
Sea water	+ krypton	<u>9</u> , 10, 11
water	+ radon-222	236, 237
water	+ xenon	147, 148
Seminal vesicles, guinea pig, see guinea pig seminal vesicles		
Silicone oil	+ xenon	192
Silver nitrate, see nitric acid, silver salt		
Small intestine, see guinea pig small intestine		
Sodium chloride (aqueous)	+ krypton	<u>12-13</u> , 20, 21
chloride (aqueous)	+ krypton-85	124 - 125
chloride (aqueous)	+ radon-222	<u>238 - 241</u> , 251
		252
chloride (aqueous)	+ xenon	149, 151 - 153
		<u>213</u> , 217, 218
chloride (aqueous)	+ xenon-133	213, 217, 218
phosphate, see phosphoric acid, sodium salt		
sulfate, see sulfuric acid, sodium salt		
Spleen, guinea pig, see guinea pig spleen		
Stomach, guinea pig, see guinea pig stomach		
Subcutaneous fat, see guinea pig subcutaneous fat		
Sucrose (aqueous)	+ radon-222	257
Sulfate, copper, see sulfuric acid, copper salt		
ferrous, see sulfuric acid iron (2+) salt		
zinc, see sulfuric acid, zinc salt		
Sulfuric acid	+ radon-219	339, 340
copper salt (aqueous)	+ radon-222	<u>238 - 241</u> , 244
iron (2+) salt	+ radon-222	<u>238 - 241</u> , 249
sodium salt	+ krypton	<u>12 - 13</u> , 22
zinc salt (aqueous)	+ radon-222	<u>238 - 241</u> , 246

T

Tallow, beef, see beef tallow		
Terphenyl	+ krypton	69
Testes, guinea pig, see guinea pig testes		
Tetrachloromethane, see methane, tetrachloro-		
Tetradecafluorocyclohexane, see cyclohexane, undecafluoro- (trifluoromethyl)-		
Tetradecane	+ krypton	48
	+ xenon	161
Tetraethyl ammonium bromide, see ethanaminium, N,N,N-triethyl-, bromide		
1,2,3,4-Tetrahydronaphthalene, see naphthalene, 1,2,3,4-tetrahydro-		
Tetralin, see naphthalene, 1,2,3,4-tetrahydro-		
Tetramethyl ammonium iodide, see methanaminium, N,N,N-trimethyl-, iodide		
Thymus, see guinea pig thymus		
Thyroid, see guinea pig thyroid		
Tissues, see guinea pig tissues, rabbit tissues		
Toluene, see benzene, methyl-		
Triacetin, see 1,2,3-propanetriol, triacetate		
Tribromomethane, see methane, tribromo-		
Tributylamine, perfluoro-, see 1-butanamine, 1,1,2,2,3,3-, 4,4,4-nonafluoro-N,N-bis(nonafluorobutyl)-		
Tributylin, see butanoic acid, 1,2,3-propanetriyl ester		

T

Trichloromethane, see methane, trichloro-
 1,1,2-Trichloro-1,2,2-trifluoroethane, see ethane, 1,1,2-trichloro-1,2,2-trifluoro-
 Tricresyl phosphate, see phosphoric acid, tris(methylphenyl) ester

Tridecane	+ krypton	47
	+ xenon	161
Tridecanoic acid	+ radon-222	309
Trihexanoic, see hexanoic acid, 1,2,3-propanetriyl ester		
1,3,5-Trimethylbenzene, see benzene, 1,3,5-trimethyl-		
2,2,4-Trimethylpentane, see pentane, 2,2,4-trimethyl-		
Trioctanoic, see octanoic acid, 1,2,3-propanetriyl ester		
Tris(methylphenyl) phosphate, see phosphoric acid, tris(methylphenyl) ester		
Turpentine	+ radon-222	327

U

Ultrasene	+ krypton	69
	+ xenon	191
Undecafluoro(trifluoromethyl)cyclohexane, see cyclohexane, undecafluoro(trifluoromethyl)-		
Undecane	+ krypton	43
	+ xenon	159
Undecanoic acid	+ radon-222	307
Unguentolan	+ radon-222	321
Uranium, dioxo (sulfato (2-) -0,0')-	+ krypton	12-13, 17, 18
dioxo (sulfato (2-) -0,0')-	+ xenon	150
(high pressure)		
Uranyl sulfate, see uranium, dioxo (sulfato (2-) -0,0')-		
Urea (aqueous)	+ radon-222	258
Uterus, see guinea pig uterus		

V

Valeric acid, see pentanoic acid		
Vaseline	+ radon-222	331
Vaseline oil	+ radon-222	334
Vitreous body, rabbit, see rabbit vitreous body		

W

Water	+ krypton	1-3, 4-8
	+ krypton-85	7, 121, 124
	+ radon-219	339, 340
	+ radon-220	343, 344
	+ radon-222	227 - 229, 230 - 234
	+ xenon (high pressure)	143 - 145
	+ xenon	134 - 136, 137 - 142, 220
	+ xenon-133	207, 214, 215, 217, 218, 225
Water-d ₂	+ radon-222	235
	+ xenon (high pressure)	146

X

o-Xylene, see benzene, 1,2-dimethyl-
 m-Xylene, see benzene, 1,3-dimethyl-
 p-Xylene, see benzene, 1,4-dimethyl-

Z

Zinc sulfate, see sulfuric acid, zinc salt
