FOREWORD

*If the knowledge is
undigested or simply wrong,
more is not better.*

The Solubility Data Series is a project of Commission V.8 (Solubility Data) of the International Union of Pure and Applied Chemistry (IUPAC). The project had its origins in 1973, when the Analytical Chemistry Division of IUPAC set up a Subcommission on Solubility Data under the chairmanship of the late Prof. A. S. Kertes. When publication of the *Solubility Data Series* began in 1979, the Committee became a full commission of IUPAC, again under the chairmanship of Prof. Kertes, who also became Editor-in-Chief of the Series. The Series has as its goal the preparation of a comprehensive and critical compilation of data on solubilities in all physical systems, including gases, liquids and solids.

The motivation for the Series arose from the realization that, while solubility data are of importance in a wide range of fields in science and technology, the existing data had not been summarized in a form that was at the same time comprehensive and complete. Existing compilations of solubility data indeed existed, but they contained many errors, were in general uncritical, and were seriously out-of-date.

It was also realized that a new series of compilations of data gave educational opportunities, in that careful compilations of existing data could be used to demonstrate what constitutes data of high and lasting quality. As well, if the data were summarized in a sufficiently complete form, any individual could prepare his or her own evaluation, independently of the published evaluation. Thus, a special format was established for each volume, consisting of individual data sheets for each separate publication, and critical evaluations for each separate system, provided sufficient data from different sources were available for comparison. The compilations and, especially, the evaluation were to be prepared by active scientists who were either involved in producing new data, or were interested in using data of high quality. With minor modifications in format, this strategy has continued throughout the Series.

In the standard arrangement of each volume, the Critical Evaluation gives the following information:

(i) A text which discusses the numerical solubility information which has been abstracted from the primary sources in the form of compilation sheets. The text concerns primarily the quality of the data, after consideration of the purity of the materials and their characterization, the experimental method used, the uncertainties in the experimental values, the reproducibility, the agreement with accepted test values, and finally, the fitting of the data to suitable functions, along with statistical tests of the fitted data.

(ii) A set of recommended data, whenever possible, including weighted averages and estimated standard deviations. If applicable, one or more smoothing equations which have been computed or verified by the evaluator are also given.

(iii) A graphical plot of the recommended data, in the form of phase diagrams where appropriate.

The Compilation part consists of data sheets which summarize the experimental data from the primary literature. Here much effort is put into obtaining complete coverage; many good data have appeared in publications from the late nineteenth and early twentieth centuries, or in obscure journals. Data of demonstrably low precision are not compiled, but are mentioned in the Critical Evaluation. Similarly, graphical data, given the uncertainty of accurate conversion to numerical values, are compiled only where no better data are available. The documentation of data of low precision can serve to alert researchers to areas where more work is needed.

A typical data sheet contains the following information:

- (i) list of components: names, formulas, Chemical Abstracts Registry Numbers;
- (ii) primary source of the data;
- (iii) experimental variables;
- (iv) compiler's name;
- (v) experimental values as they appear in the primary source, in modern units with explanations if appropriate;
- (vi) experimental methods used;
- (vii) apparatus and procedure used;
- (viii) source and purity of materials used;
- (ix) estimated error, either from the primary source or estimated by the compiler;
- (x) references relevant to the generation of the data cited in the primary source.

Each volume also contains a general introduction to the particular type of system, such as solubility of gases, of solids in liquids, etc., which contains a discussion of the nomenclature used, the principle of accurate determination of solubilities, and related thermodynamic principles. This general introduction is followed by a specific introduction to the subject matter of the volume itself.

The Series embodies a new approach to the presentation of numerical data, and the details continue to be influenced strongly by the perceived needs of prospective users. The approach used will, it is hoped, encourage attention to the quality of new published work, as authors become more aware that their work will attain permanence only if it meets the standards set out in these volumes. If the Series succeeds in this respect, even partially, the Solubility Data Commission will have justified the labour expended by many scientists throughout the world in its production.

January, 1989

J. W. Lorimer,

PREFACE

This volume of The Solubility Data Series contains evaluated data for the solubility in non-aqueous solvents of carbon dioxide at a partial pressure not greater than 200 kPa. In some cases a compiler has extrapolated published data for higher pressures to obtain a value for a solubility at a pressure below 200 kPa. Two further volumes in the series will include data for aqueous systems at all pressures and data for non-aqueous systems at pressures above 200 kPa.

Measurements of the solubility of carbon dioxide have been carried out for over a hundred years. New techniques have been developed and old techniques modified during this time but some of the early measurements are in close agreement with recent measurements. Reliance may be placed on data when there is good agreement between the measurements of different groups of workers. Unfortunately there are sometimes inconsistencies between measurements by different groups. Judgements have then to be made of the relative reliability of different experimental methods. Difficulties in attaining equilibrium between the gas and liquid phase are an important cause of discrepancies.

In some cases it has been possible to recommend equations relating mole fraction solubility at a partial pressure of 101.3 kPa with temperature. These equations are based on the data which have been considered to be the most reliable. The use of these equations for extrapolation more than a few degrees outside the temperature range of the experimental measurements can lead to errors.

The editor is grateful for support, encouragement and help from fellow members of the IUPAC Commission on Solubility Data. He would like to acknowledge the help given by Dr Elena Gryzlova in obtaining copies of papers from the less accessible Russian journals. He would also like to thank Dr Sim-wan Annie Bligh for her assistance in translating Chinese and Japanese papers.

WILLIAM GERRARD 1900-1990

Members of the Solubility Data Commission of the International Union of Pure and Applied Chemistry were saddened by the death of Dr William Gerrard on 5th February 1990, shortly before his ninetieth birthday. William Gerrard was the oldest and one of the longest serving members of the Commission.

William Gerrard was born in Tyldesley, Lancashire, U.K. on 24th February, 1900. He studied part-time at a local technical college and eventually graduated as an external student of the University of London with first class honours in chemistry. Later he gained a PhD after part-time research at Battersea Polytechnic in London under the direction of Dr Joseph Kenyon, FRS. This gave him a life long interest in the mechanisms and stereochemistry of reactions of esters of phosphorus and sulfur. William Gerrard joined the staff of the Northern Polytechnic (now Polytechnic of North London) in 1934 after holding earlier academic posts. He became Head of the Department of Chemistry, Mathematics, Botany, Zoology, Biology and Geology in 1948, a post which he held until he retired in 1965.

During the Second World War he had responsibilities for a section of the London University Air Squadron training at the Northern Polytechnic and held the rank of Flight Lieutenant.

It is as an experimental organic chemist that he made his most important contribution to chemistry. He established a flourishing research school covering a wide range of organic chemistry and published over 200 research papers. He was awarded the degree of DSc in 1947. His monograph *The Organic Chemistry of Boron* was published in 1961. He also contributed a chapter on boron chemistry to *Mellor's Inorganic Chemistry* and a chapter on the organic chemistry of phosphorous and thiophosphorous acids to the Kosolapoff and Maier series *Organic Compounds of Phosphorus*. For many years after his retirement he continued to direct the studies of part time and full time research students and to work at the bench himself. His interest in solubility phenomena arose from his observations of the behaviour of gases such as hydrogen chloride and sulfur dioxide during organic reactions in the liquid phase. As his many research students and collaborators can testify, once William Gerrard's enthusiasm was roused he had the ability to transmit his enthusiasm to others.

He and his co-workers published many papers containing solubility data for the hydrogen halides and other gases. His book entitled *Solubility of Gases and Liquids* was published in 1976. *Gas Solubilities - Widespread Applications* followed in 1980. At the time of his death he was co-operating with Peter Fogg in the preparation of *Solubility of Gases in Liquids* which was published later in the year.

Publications on the solubility of gases led to an invitation to assist in the Solubility Data Project shortly after its inception and continued to serve when Commission status was achieved in 1979. He contributed to several of the volumes on gas solubilities and was co-editor of *Hydrogen Halides in Non-aqueous Solvents*. He was always fearless in his determination to maintain high standards. Not one of his colleagues working in the Solubility Data Commission could escape his criticism if things did not meet his approval. Eventually failing hearing and eyesight and general frailty made it impossible for him to attend annual meetings of the Solubility Data Commission. Until the last he took a keen interest in the affairs of the Commission and continued to provide detailed comments.

He was awarded an OBE for services to chemistry in 1981.

William Gerrard had an infectious delight in many aspects of chemistry and former colleagues and students have been inspired by his unforgettable enthusiasms, scholarship and devotion to hard and careful work. It is a privilege to have worked with him.

THE SOLUBILITY OF GASES IN LIQUIDS

R. Battino, H. L. Clever and C. L. Young

INTRODUCTION

The Solubility Data Project aims to make a comprehensive search of the literature for data on the solubility of gases, liquids and solids in liquids. Data of suitable accuracy are compiled into data sheets set out in a uniform format. The data for each system are evaluated and where data of sufficient accuracy are available values recommended and in some cases a smoothing equation suggested to represent the variation of solubility with pressure and/or temperature. A text giving an evaluation and recommended values and the compiled data sheets are published on consecutive pages.

DEFINITION OF GAS SOLUBILITY

The distinction between vapor-liquid equilibria and the solubility of gases in liquids is arbitrary. It is generally accepted that the equilibrium set up at 300K between a typical gas such as argon and a liquid such as water is gas liquid solubility whereas the equilibrium set up between hexane and cyclohexane at 350K is an example of vapor-liquid equilibrium. However, the distinction between gas-liquid solubility and vapor-liquid equilibrium is often not so clear. The equilibria set up between methane and propane above the critical temperature of methane and below the critical temperature of propane may be classed as vapor-liquid equilibrium or as gas-liquid solubility depending on the particular range of pressure considered and the particular worker concerned.

The difficulty partly stems from our inability to rigorously distinguish between a gas, a vapor, and a liquid, which has been discussed in numerous textbooks. We have taken a fairly liberal view in these volumes and have included systems which may be regarded, by some workers, as vapor-liquid equilibria.

UNITS AND QUANTITIES

The solubility of gases in liquids is of interest to a wide range of scientific and technological disciplines and not solely to chemistry. Therefore a variety of ways for reporting gas solubility have been used in the primary literature and inevitably sometimes, because of insufficient available information, it has been necessary to use several quantities in the compiled tables. Where possible, the gas solubility has been quoted as a mole fraction of the gaseous component in the liquid phase. The units of pressure used are bar, pascal, millimeters of mercury and atmosphere. Temperatures are reported in Kelvin.

EVALUATION AND COMPILATION

The solubility of comparatively few systems is known with sufficient accuracy to enable a set of recommended values to be presented. This is true both of the measurement near atmospheric pressure and at high pressures. Although a considerable number of systems have been studied by at least two workers, the range of pressures and/or temperatures is often sufficiently different to make meaningful comparison impossible.

Occasionally, it is not clear why two groups of workers obtained very different sets of results at the same temperature and pressure, although both sets of results were obtained by reliable methods and are internally consistent. In such cases, sometimes an incorrect assessment has been given. There are several examples where two or more sets of data have been classified as tentative although the sets are mutually inconsistent.

Many high pressure solubility data have been published in a smoothed form. Such data are particularly difficult to evaluate, and unless specifically discussed by the authors, the estimated error on such values can only be regarded as an "informed guess".

Many of the high pressure solubility data have been obtained in a more general study of high pressure vapor-liquid equilibrium. In such cases a note is included to indicate that additional vapor-liquid equilibrium data are given in the source. Since the evaluation is for the compiled data, it is possible that the solubility data are given a classification which is better than that which would be given for the complete vapor-liquid data (or vice versa). For example, it is difficult to determine coexisting liquid and vapor compositions near the critical point of a mixture using some widely used experimental techniques which yield accurate high pressure solubility data. For example, conventional methods of analysis may give results with an expected error which would be regarded as sufficiently small for vapor-liquid equilibrium data but an order of magnitude too large for acceptable high pressure gas-liquid solubility.

It is occasionally possible to evaluate data on mixtures of a given substance with a member of a homologous series by considering all the available data for the given substance with other members of the homologous series. In this study the use of such a technique has been very limited.

The estimated error is often omitted in the original article and sometimes the errors quoted do not cover all the variables. In order to increase the usefulness of the compiled tables estimated errors have been included even when absent from the original article. If the error on *any* variable has been inserted by the compiler this has been noted.

PURITY OF MATERIALS

The purity of materials has been quoted in the compiled tables where given in the original publication. The solubility is usually more sensitive to impurities in the gaseous component than to liquid impurities in the liquid component. However, the most important impurities are traces of a gas dissolved in the liquid. Inadequate degassing of the absorbing liquid is probably the most often overlooked serious source of error in gas solubility measurements.

APPARATUS AND PROCEDURES

In the compiled tables brief mention is made of the apparatus and procedure. There are several reviews on experimental methods of determining gas solubilities and these are given in References 1-7.

METHODS OF EXPRESSING GAS SOLUBILITIES

Because gas solubilities are important for many different scientific and engineering problems, they have been expressed in a great many ways:

The Mole Fraction, $x(g)$

The mole fraction solubility for a binary system is given by:

$$x(g) = \frac{n(g)}{n(g) + n(l)}$$

$$= \frac{W(g)/M(g)}{[W(g)/M(g)] + [W(l)/M(l)]}$$

here n is the number of moles of a substance (an *amount* of substance), W is the mass of a substance, and M is the molecular mass. To be unambiguous, the partial pressure of the gas (or the total pressure) and the temperature of measurement must be specified.

The Weight Per Cent Solubility, wt%

For a binary system this is given by

$$\text{wt\%} = 100 W(g)/[W(g) + W(l)]$$

where W is the weight of substance. As in the case of mole fraction, the pressure (partial or total) and the temperature must be specified. The weight per cent solubility is related to the mole fraction solubility by

$$x(g) = \frac{[\text{wt}\%/M(g)]}{[\text{wt}\%/M(g)] + [(100 - \text{wt}\%)/M(l)]}$$

The Weight Solubility, C_w

The weight solubility is the number of moles of dissolved gas per gram of solvent when the partial pressure of gas is 1 atmosphere. The weight solubility is related to the mole fraction solubility at one atmosphere partial pressure by

$$x(g) \text{ (partial pressure 1 atm)} = \frac{C_w M(l)}{1 + C_w M(l)}$$

where $M(l)$ is the molecular weight of the solvent.

The Moles Per Unit Volume Solubility, n

Often for multicomponent systems the density of the liquid mixture is not known and the solubility is quoted as moles of gas per unit volume of liquid mixture. This is related to the mole fraction solubility by

$$x = \frac{n v^O(l)}{1 + n v^O(l)}$$

where $v^O(l)$ is the molar volume of the liquid component.

The Bunsen Coefficient, α

The Bunsen coefficient is defined as the volume of gas reduced to 273.15K and 1 atmosphere pressure which is absorbed by unit volume of solvent (at the temperature of measurement) under a partial pressure of 1 atmosphere. If ideal gas behavior and Henry's law is assumed to be obeyed,

$$\alpha = \frac{V(g)}{V(l)} \frac{273.15}{T}$$

where $V(g)$ is the volume of gas absorbed and $V(l)$ is the original (starting) volume of absorbing solvent. The mole fraction solubility is related to the Bunsen coefficient by

$$x(g, 1 \text{ atm}) = \frac{\alpha}{\alpha + \frac{273.15}{T} \frac{v^O(g)}{v^O(l)}}$$

where $v^O(g)$ and $v^O(l)$ are the molar volumes of gas and solvent at a pressure of one atmosphere. If the gas is ideal,

$$x(g) = \frac{\alpha}{\alpha + \frac{273.15R}{v^O(l)}}$$

Real gases do not follow the ideal gas law and it is important to establish the real gas law used for calculating α in the original publication and to make the necessary adjustments when calculating the mole fraction solubility.

The Kuenen Coefficient, S

This is the volume of gas, reduced to 273.15K and 1 atmosphere pressure, dissolved at a partial pressure of gas of 1 atmosphere by 1 gram of solvent.

The Ostwald Coefficient, L

The Ostwald coefficient, L, is defined as the ratio of the volume of gas absorbed to the volume of the absorbing liquid, all measured at the same temperature.

$$L = \frac{V(g)}{V(l)}$$

If the gas is ideal and Henry's Law is applicable, the Ostwald coefficient is independent of the partial pressure of the gas. It is necessary, in practice, to state the temperature and total pressure for which the Ostwald coefficient is measured. The mole fraction solubility, x , is related to the Ostwald coefficient by

$$x(g) = \frac{RT}{P(g) L v^O(l)} + 1 \quad -1$$

where P is the partial pressure of gas. The mole fraction solubility will be at a partial pressure of P(g).

The Absorption Coefficient, β

There are several "absorption coefficients", the most commonly used one being defined as the volume of gas, reduced to 273.15K and 1 atmosphere, absorbed per unit volume of liquid when the total pressure is 1 atmosphere. β is related to the Bunsen coefficient by

$$\beta = \alpha (1 - P(l))$$

where P(l) is the partial pressure of the liquid in atmosphere.

The Henry's Law Constant

A generally used formulation of Henry's Law may be expressed as

$$P(g) = K_H x(g)$$

where K_H is the Henry's Law constant and x the mole fraction solubility. Other formulations are

$$P(g) = K_2 C(l)$$

or

$$C(g) = K_c C(l)$$

where K_2 and K_c are constants, C the concentration, and (l) and (g) refer to the liquid and gas phases. Unfortunately, K_H , K_2 , and K_c are all sometimes referred to as Henry's Law constants. Henry's Law is a limiting law but can sometimes be used for converting solubility data from the experimental pressure to a partial gas pressure of 1 atmosphere, provided the mole fraction of the gas in the liquid is small, and that the difference in pressures is small. Great caution must be exercised in using Henry's Law.

The Mole Ratio, N

The mole ratio, N, is defined by

$$N = n(g)/n(l)$$

Table 1 contains a presentation of the most commonly used inter-conversions not already discussed.

For gas solubilities greater than about 0.01 mole fraction at a partial pressure of 1 atmosphere there are several additional factors which must be taken into account to unambiguously report gas solubilities. Solution densities or the partial molar volume of gases must be known. Corrections should be made for the possible non-ideality of the gas or the non-applicability of Henry's Law.

TABLE 1. Interconversion of parameters used for reporting solubility.

$$L = \alpha(T/273.15)$$

$$C_w = \alpha/v_o\rho$$

$$K_H = \frac{17.033 \times 10^6 \rho(\text{soln})}{\alpha M(l)} + 760$$

$$L = C_w v_{t,\text{gas}} \rho$$

where v_o is the molal volume of the gas in $\text{cm}^3 \text{mol}^{-1}$ at 0°C , ρ the density of the solvent at the temperature of the measurement, ρ_{soln} the density of the solution at the temperature of the measurement, and $v_{t,\text{gas}}$ the molal volume of the gas ($\text{cm}^3 \text{mol}^{-1}$) at the temperature of the measurement.

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Alkanes, Cyclic Alkanes and Alkenes	July 1991

CRITICAL EVALUATION:

Solubility of carbon dioxide in alkanes, cyclic alkanes and alkenes.

The solubility of solid carbon dioxide in methane, ethane, propane and butane was measured by Cheung and Zander (1) at temperatures between 87.4 K and 194.6 K. Solubility in methane at 126.4 K and 137.5 K was measured by Preston *et al.* (2). There is satisfactory agreement with Cheung's data. The concentration of carbon dioxide in solution in the presence of solid carbon dioxide increases with increase in temperature. The partial vapor pressure also increases with temperature and mole fraction solubilities corrected to the same partial vapor pressure show a decrease with increase in temperature in line with the behaviour of the gas in other solvents. Data indicate that there are insignificant differences between solubilities in methane, propane and butane under the conditions of the measurements but that solubility is greatest in ethane. (see table below)

alkane	T/K	mole% of CO ₂ in solution
methane	183.2	6.60
	183.2	5.85
ethane	180.3	7.54
propane	180.2	5.7
butane	180.3	5.6

Solubility of solid carbon dioxide in liquid ethane was also measured by Clark and Din (3) from 130 K to 180 K. Clark's measurements are close to those of Cheung at lower temperatures. Clark found a solubility of 0.9 mol% at 150 K and Cheung a value of 0.85 mol% at 149 K. The agreement at higher temperatures is poor. Clark's value for 180 K is 6.7 mol% and Cheung's value at 180.3 K is 7.54 mol%

Nagahama *et al.* (4) studied phase equilibria between gaseous carbon dioxide and ethane, propane, butane or 2-methylpropane. Measurements were extended to high pressures over the whole concentration range. Approximate mole fraction solubilities for a partial pressure of 101.3 kPa show an increase with carbon number at constant temperature. These have been estimated by the evaluator from data for partial pressures of carbon dioxide from 71 to 214 kPa, assuming that mole fraction solubility is proportional to pressure, and are given below.

alkane	T/K	x _{CO₂}
ethane	252.95	0.026
propane	252.95	0.029
	273.15	0.019
butane	273.15	0.021
	273.15	0.019
2-methylpropane	273.15	0.019

Makranczy *et al.* (5) measured the solubility of carbon dioxide in straight chain alkanes from pentane to hexadecane at 298.2 K and 313.2 K. These measurements show a decrease in mole fraction solubility with increase in chain length at a partial pressure of gas of 101.3 kPa. This is not in accord with measurements reported by other workers and the bulk of evidence indicates that mole fraction solubility increases with chain length.

Solubility in pentane has been reported by Makranczy *et al.* (5) and by Cheng *et al.* (6). Cheng's data indicate a mole fraction solubility of approximately 0.0138 at 298.2 K and a partial pressure of carbon dioxide of 101.3 kPa. The mole fraction solubility from Makranczy's measurements under these conditions is 0.01258. The following equation for mole

Holloway Road, London, N7 8DB, U.K.

July 1991

CRITICAL EVALUATION:

Fig. 1 Variation with temperature of the mole fraction solubility of carbon dioxide in hexane at a partial pressure of gas of 101.3 kPa.

Points based upon experiemntal measurements by various authors (5,8-13) have been superimposed on a curve corresponding to the equation

$$\ln x_{\text{CO}_2} = 26.213 - 429.93/(T/K) - 5.1244 \ln(T/K)$$

A reference line corresponding to values from the Raoult's law equation is also shown.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alkanes, Cyclic Alkanes and Alkenes 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>pressure of gas of 101.2 kPa from these three sets of data fit the equation</p> $\ln x_{\text{CO}_2} = -9.6225 + 1063.4/(T/K) + 0.2883 \ln(T/K)$ <p>temperature range = 238.2-313.4 K standard deviation in x_{CO_2} = 6.2×10^{-5}</p> <p>The mole fraction solubility at 298.15 K published by Tong <i>et al.</i> (14) is close to the value from this equation (Tong 0.0119; eqn. 0.0121). Mole fraction solubilities at 298.15 and 313.15 K calculated from data given by Makranczy <i>et al.</i> (5), fall below values given by the equation.</p> <p>Asano <i>et al.</i> (18) used a chromatographic method to measure <i>K</i>-values for dissolution of carbon dioxide in solutions of methane in octane. The <i>K</i>-values were defined as the ratio of mole fractions of CO₂ in the vapor and in the liquid phases and correspond to very low concentrations of carbon dioxide. The data are self-consistent but no other data on this system are available for comparison.</p> <p>Hiraoka and Hildebrand (19) measured solubility in the non-linear 2,2,4-trimethylpentane. The mole fraction solubility at 298.15 and a partial pressure of 101.3 kPa estimated from these data is 0.0139 compared with a value for solubility in octane from the above equation of 0.0121. This difference may be compared with that between solubilities in pentane and 2,2-dimethylpropane which has been noted above.</p> <p>Solubility in nonane was measured by Makranczy <i>et al.</i> (5). Measurements of solubilities of carbon dioxide in the higher alkanes by this group do not conform to the general trend indicated by other workers. A value for 298.15 K has also been published by Tong <i>et al.</i> (14). The data for nonane cannot be recommended until they are substantiated by other measurements on this system.</p> <p>Solubility in decane has been measured by Wilcock <i>et al.</i> (17), King and Al-Najjar (10), Horvath <i>et al.</i> (20), Makranczy <i>et al.</i> (5), and Tong <i>et al.</i> (14). The following equation for mole fraction solubility at a partial pressure of 101.3 kPa is based upon data from the first three groups of workers.</p> $\ln x_{\text{CO}_2} = 14.481 - 114.51/(T/K) - 3.2438 \ln(T/K)$ <p>temperature range = 283.2-313.5 K. standard deviation in x_{CO_2} = 0.00016</p> <p>Data published by Makranczy and by Tong are not consistent with this equation.</p> <p>Values of the solubility in undecane, tridecane and pentadecane reported by Makranczy <i>et al.</i> appear to be too low and cannot be recommended until the measurements have been repeated by other workers. The mole fraction solubility in undecane at 298.15 K has been published by Tong <i>et al.</i> In contrast this value appears to be too high in comparison with data for other alkanes.</p> <p>Solubility in dodecane has been measured by Hayduk <i>et al.</i> (16), by King and Al-Najjar (10) and by Makranczy <i>et al.</i> (5). Measurements by Hayduk are consistent with those by King. Mole fraction solubilities at a partial pressure of 101.3 kPa from these two sources fit the equation</p> $\ln x_{\text{CO}_2} = 11.161 + 66.063/(T/K) - 2.7623 \ln(T/K)$ <p>temperature range = 283.15-323.15 K standard deviation in x_{CO_2} = 0.00014</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alkanes, Cyclic Alkanes and Alkenes 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubilities measured by Macranczy <i>et al.</i> are about 14% lower than those reported by the other authors.</p> <p>Mole fraction solubility in tetradecane at a partial pressure of 101.3 kPa from measurements by King and Al-Najjar (10) fit the equation</p> $\ln x_{\text{CO}_2} = -49.650 + 2870.5/(T/K) + 6.2703 \ln(T/K)$ <p>temperature range = 298.2-343.2 K standard deviation in $x_{\text{CO}_2} = 1.2 \times 10^{-5}$</p> <p>Measurements by Makranczy <i>et al.</i> (5) are about 20% lower and are less likely to be reliable.</p> <p>Solubility in hexadecane has been measured by at least seven groups (5,10,16, 21-24). Measurements by Macranczy <i>et al.</i> appear to be too low and those by Lenoir <i>et al.</i> (21) to be too high. Values of mole fraction solubility from measurements by the other groups are mutually consistent and fit the equation</p> $\ln x_{\text{CO}_2} = -26.045 + 1769.0/(T/K) + 2.7810 \ln(T/K)$ <p>temperature range = 298.2-475.0 K standard deviation in $x_{\text{CO}_2} = 0.00015$</p> <p>The solubility in heptadecane at 313.2 K was measured by Lenoir <i>et al.</i> (21) using a chromatographic method to find the limiting value of Henry's constant. The corresponding value of the mole fraction solubility at 101.3 kPa is 0.0139. This may be compared with the value of 0.01210 for solubility in hexadecane at this temperature and pressure from the equation given above.</p> <p>Henry's law constants for dissolution of carbon dioxide in eicosane (C₂₀H₄₂) were measured by Chai and Paulaitis (24), Gasem and Robinson (25) and by Huang <i>et al.</i> The sets of data are mutually consistent. The corresponding mole fraction solubilities for a partial pressure of 101.3 kPa fit the equation</p> $\ln x_{\text{CO}_2} = -23.875 + 1622.2/(T/K) + 2.5006 \ln(T/K)$ <p>temperature range = 313.2-573.4 K standard deviation in $x_{\text{CO}_2} = 0.00044$</p> <p>Solubility in octacosane (C₂₈H₅₈) was reported by Huang <i>et al.</i> (26), Gasem and Robinson (25) and by Lin and Parcher (22) with good agreement between the sets of data. Mole fraction solubilities at a partial pressure of 101.3 kPa fit the equation</p> $\ln x_{\text{CO}_2} = -25.506 + 1747.4/(T/K) + 2.7523 \ln(T/K)$ <p>temperature range = 348.2-573.2 K standard deviation in $x_{\text{CO}_2} = 4.2 \times 10^{-5}$</p> <p>Solubilities in hexatriacontane (C₃₆H₇₄) have also been published by Gasem and Robinson (25) and by Lin and Parcher (22). There is again good agreement between sets of data. Mole fraction solubilities at a partial pressure of 101.3 kPa fit the equation</p> $\ln x_{\text{CO}_2} = 5.2340 + 123.53/(T/K) - 1.6712 \ln(T/K)$ <p>temperature range = 353.2-423.2 K standard deviation in $x_{\text{CO}_2} = 0.00014$</p>	

COMPONENTS:

1. Carbon dioxide; CO₂; [124-38-9]
2. Alkanes, Cyclic Alkanes and Alkenes

EVALUATOR:

Peter G.T. Fogg,
 School of Applied Chemistry,
 Polytechnic of North London,
 Holloway Road, London, N7 8DB, U.K.
 July 1991

CRITICAL EVALUATION:

Fig. 2 Selected values of the mole fraction solubility of carbon dioxide in straight chain alkanes at 298.15 K or 373.15 K and a partial pressure of gas of 101.3 kPa.

large crosses 298.15 K
 small crosses 373.15 K

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Alkanes, Cyclic Alkanes and Alkenes	July 1991

CRITICAL EVALUATION:

Gasem and Robinson (25) measured solubility in tetratetracontane (C₄₄H₉₀) at 373.2 and 423.2 K. Mole fraction solubilities for a partial pressure of 101.3 kPa are in accord with the general trend of values with increase in chain length (see fig 2).

Chai and Paulaitis (24) have published Henry's constants at infinite dilution for the carbon dioxide - squalane (C₃₀H₆₂) system for 298.6-330.2 K. Mole fraction solubilities at a partial pressure of 101.3 kPa estimated from these constants fit the equation

$$\ln x_{\text{CO}_2} = -16.170 + 1354.4/(T/K) + 1.3729 \ln(T/K)$$

temperature range = 298.6-330.2 K

standard deviation in x_{CO_2} = 0.00011

A plot of the mole fraction solubility at 101.3 kPa against temperature lies close to an extrapolation of a similar plot for hexatriacontane. Mole fraction solubilities are higher than extrapolated values for octacosane (Fig 3).

Phase equilibria between cyclopropane and carbon dioxide has been studied by Haselden and Snowden (27). They reported dew and bubble points from 179 K to 237 K. Data are self-consistent. The mole fraction solubility at 228.3 K and a partial pressure of carbon dioxide of approximately 99.51 kPa is 0.0489. This may be compared with the ideal solubility of 0.119 estimated from Raoult's law.

Mole fraction solubilities in cyclic alkanes are lower than in the corresponding straight chain compounds. Eckert and Sandler (28) studied equilibria between cyclopentane and carbon dioxide at 310.9 K to 333.2 K and pressures to 8263 kPa. The mole fraction solubility at 310.9 K and a partial pressure of carbon dioxide of 101.3 kPa from this work is 0.0065. The corresponding value for solubility in pentane from the smoothing equation given above is 0.0104. The ideal solubility from Raoult's law is 0.0118.

At least nine groups have measured solubility in cyclohexane (8,9,12,15, 29-33). Solubility at 293.2 K reported by Horsman-van den Dool and Warman (12) was measured by an unsatisfactory method and is not consistent with measurements by other workers. Mole fraction solubility at a partial pressure of 101.3 kPa from other sources fit the equation below.

$$\ln x_{\text{CO}_2} = 0.11850 + 454.47/(T/K) - 1.1454 \ln(T/K)$$

temperature range = 283.2-313.2 K

standard deviation in x_{CO_2} = 0.00016

The mole fraction solubility at 298.15 from this equation is 0.00757. The corresponding smoothed value for solubility in hexane is 0.01196.

Field *et al.* (34) measured solubility in methylcyclohexane at 283.9-313.3 K. Horsman-van den Dool (12) also reported a value at 294.3 which is about 5% lower than the corresponding value from data published by Field *et al.* Field's value is the more reliable and can be recommended. The mole fraction solubility at 298.13 K and a partial pressure of 101.3 kPa from Field's work is 0.00928 compared with a smoothed value of 0.01188 for dissolution in heptane.

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Alkanes, Cyclic Alkanes and Alkenes	July 1991

CRITICAL EVALUATION:

Wilcock *et al.* (35) measured the solubility in cyclooctane at 289.1-313.5 K. No other data on this system are available for comparison but this work is likely to be reliable. The mole fraction solubility at a partial pressure of 101.3 kPa and 298.27 K is 0.006860 compared with a smoothed value of 0.01210 for dissolution in octane under these conditions.

Geller *et al.* (36) measured solubilities in various isomers of dimethylcyclohexane. The work is likely to be reliable but no other work on these systems is available for comparison. Mole fraction solubilities, corrected to 298.15 K and a partial pressure of 101.3 kPa are given below together with the smoothed value for octane.

(Z)-1,2-dimethylcyclohexane	0.00938
(E)-1,2-dimethylcyclohexane	0.01020
1,3-dimethylcyclohexane	
(59 mol% Z + 41 mol% E)	0.01021
1,4-dimethylcyclohexane	
(70 mol% Z + 30 mol% E)	0.01035
octane	0.01211

There is a significant difference between solubilities in (Z)- and (E)-1,2-dimethylcyclohexane.

Tremper and Prausnitz (23) published Henry's constants in 1,1'-bicyclohexyl from 300 K to 475 K. Horsman-van den Dool reported an Ostwald coefficient at 295.2 K. This corresponds to a mole fraction solubility at a partial pressure of 101.3 kPa of 0.00854. Extrapolation of Tremper's measurements indicates a mole fraction solubility of 0.00820 at 295.2 K and 101.3 K. Horsman-van den Dool used very simple apparatus and Tremper's data are likely to be the more reliable.

Solubility in decahydronaphthalene (decalin) was measured by Luhning and Schumpe (33) and by Horsman-van den Dool and Warman (12). The former group used a mixture of isomers and the latter made separate measurements on the two isomers. Lenoir *et al.* (21) measured limiting values of Henry's constant for a mixture of isomers by gas-liquid chromatography. Mole fraction solubilities at a partial pressure of 101.3 kPa from the available data are as follows

mixed isomers	293.2 K	0.00790	(33)
	298.2	0.00909	(21)
	323.2	0.00735	(21)
(Z)-decalin	296.6 K	0.00697	(12)
(E)-decalin	296.6 K	0.00816	(12)

Further measurements on this system need to be made before solubility data can be recommended.

Nagahama *et al.* (4) have studied phase equilibria between ethene and carbon dioxide to high pressures. At 252.95 K the mole fraction solubility in ethene at a partial pressure of carbon dioxide of 183 kPa is 0.071. This may be compared with their value of 0.055 for the mole fraction solubility in ethane at 252.95 K and a partial pressure of carbon dioxide of 214 kPa. Clark and Din (3) measured the solubility of solid carbon dioxide in liquid ethene and in various mixtures with ethane at 130-180 K. Under these conditions carbon dioxide was again more soluble in ethene than in ethane.

Haselden and Snowden (27) have reported dew points and bubble points for mixtures of carbon dioxide and propene at 116-225 K. Phase equilibria in

COMPONENTS:

Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.
July 1991

CRITICAL EVALUATION:

Fig. 3 Mole fraction solubility of carbon dioxide in various alkanes and cyclic alkanes at a partial pressure of gas of 101.3 kPa.

The curves showing the variation of solubility with temperature correspond to equations derived by the evaluator. The solubility of methylcyclohexane is from ref. (34).

A reference line corresponding to values from the Raoult's law equation is also shown.

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Alkanes, Cyclic Alkanes and Alkenes	July 1991

CRITICAL EVALUATION:

this system have also been studied to high pressure by Nagahama *et al.*(4) Cheung and Zander (1) have measured solubilities of solid carbon dioxide in propene. There is no obvious incompatibility between the three sets of measurements. Nagahama's measurements indicate a mole fraction solubility of 0.076 at 252.95 K and a partial pressure of carbon dioxide of 184 kPa and a solubility of 0.014 at 273.15 and a partial pressure of 81 kPa. The corresponding ideal solubilities from Raoult's law are 0.094 and 0.023

Nagahama *et al.*(4) also studied phase equilibria between carbon dioxide and 1-butene to high pressures. The mole fraction solubilities of carbon dioxide given below are based upon their data and show an increase from ethene to 1-butene.

Hydrocarbon	T/K	P/kPa	x _{CO₂}
ethene	252.95	183	0.071
propene	252.95	184	0.076
	273.15	219	0.050
1-butene	273.15	193	0.059

Luhring and Schumpe (33) have published Henry's constant for dissolution in 1-tetradecene at 293.2 K. This corresponds to a mole fraction solubility of 0.001654 at a partial pressure of 101.3 kPa. The corresponding value for dissolution in tetradecane is 0.01442.

Solubility in tetrahydronaphthalene has been measured by Luhring and Schumpe (33), by Horvath *et al.*(20), by Krauss and Gestrich (32) and by Bratzler *et al.*(37). The seven data points for mole fraction solubility at a partial pressure of 101.3 kPa fit the equation below.

$$\ln x_{\text{CO}_2} = 22.419 - 306.70/(T/K) - 4.6125 \ln(T/K)$$

temperature range = 283.15-313.15 K.
standard deviation in values of x_{CO₂} = 0.00031

The mole fraction solubility at 293.15 K from this equation is 0.00799 ± 0.00034. The value for 296.6 K is 0.00766 ± 0.00034. These may be compared with solubility data for decahydronaphthalene given above. Further measurements are needed to determine the relative solubilities in the two solvents.

Just (38) measured solubility in 1-methyl-4-(1-methylethenyl)cyclohexene (*d-limonene*, *carvene*). No other measurements on this compound are available for comparison.

Selected values of mole fraction solubilities in non-aromatic hydrocarbons are shown in Table 1 and Fig 3.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
Mixtures of carbon dioxide and the hydrocarbon gas under test flowed through a cell held in a cryostat. The carbon dioxide was in excess so that a solution of carbon dioxide and solid carbon dioxide condensed in the cell. Samples of the solution were withdrawn into a sample bulb through a fritted disc of fine porosity so that particles of solid were held back. The samples were then vaporized and analysed by gas chromatography. Some samples were also analysed by mass spectrometry. The authors claim good agreement between the two methods of analysis. Typical values given by the authors are within about 2% except at low concentration. Most of the measurements on solvents other than methane were made at a pressure less than 101.3 kPa using glass apparatus. Stainless steel apparatus was used for higher pressures.	No information

AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:			
The data given above were obtained during studies of the systems to higher pressures over the whole of each composition range. The apparatus has been described previously (1). The components were charged into a glass-windowed equilibrium cell. A magnetic piston pump recirculated vapor, removed it from the top of the liquid and reintroduced it into the bottom of the liquid. After equilibrium was reached (c. 0.5 h) samples of the gas phase and of the liquid phase were analysed by gas chromatography.			1. Purity at least 99.8%

x _{CO₂} is the mole fraction of CO ₂ in the liquid phase. y _{CO₂} is the mole fraction of CO ₂ in the gas phase * calculated by the compiler and taken to be y _{CO₂} × total pressure				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
A mixture of carbon dioxide and 2,2-dimethylpropane was circulated through a thermostatted equilibrium cell. The rest of the apparatus was at a higher temperature so that condensation occurred only in the cell. Samples of liquid in the cell and vapor circulating through the system were analysed by gas chromatography.		1 Supplied by The Distillers Company; purity stated to be better than British Standard 4105 (1967). 2 Supplied by Fisons Scientific Apparatus Ltd; purity at least 99%.		
ESTIMATED ERROR: δP/kPa = ±1.4; δT/K = ±0.008 (T/K<273); δT/K = ±0.010 (T/K>273) δ(mole fraction) = ±0.01 at mole fractions close to 0.5 δ(mole fraction) = ±0.003 at mole fractions close to 0.01 or 0.99

* Estimated by the compiler by use of a Krichevsky-Il'inskaya equation from the solubility data for 2-10 atm given in the paper.																																		
AUXILIARY INFORMATION																																		
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																																	
Details of method given in ref. (1). A static method was used. A glass (low pressure) section of the apparatus was connected to a high pressure section made of metal. Carbon dioxide in the low pressure section was allowed to condense in a cooled metal bulb in the high pressure section. The quantity of gas collected was found from pressure changes in the glass section. The valve connecting the two section was then closed and the condensed gas allowed to evaporate to generate the required pressure and to come in contact with the solvent under test which was held in an absorption cell in a thermostat bath. The cell was stirred magnetically. The quantity of unabsorbed gas when equilibrium was reached was calculated from the final pressure and volume of the gas in the high pressure section. * vapor pressure of solid CO ₂ from ref. (1).			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility of solid carbon dioxide was measured as described earlier (2). The components were introduced into the glass cell and 1 to 2 hr allowed for equilibrium to be reached. Samples of liquid were withdrawn at various temperatures from the glass equilibrium cell for analysis by gas chromatography. Alternatively the equilibrium temperature of mixtures of known composition were measured. Temperatures were controlled by an air bath cooled by liquid nitrogen and measured by a calibrated platinum resistance thermometer. Pressures were measured by a calibrated Heise gage.		1. Coleman Instrument grade obtained from Matheson Gas Products. Analysis showed that the purity was better than 99.9%	
		2. Supplied by Phillips Petroleum Co. Analysis showed that the purity was better than 99.9%

METHOD/APPARATUS/PROCEDURE: A cylindrical glass container of approximately 15 cm^3 volume is partly filled with solvent and closed with a half-hole septum. An amount of the gaseous solute is added to the container. The closed container is shaken for 30 minutes. Samples of both the vapor and liquid phases are taken in a calibrated syringes. The samples are injected into a gas chromatograph. The Ostwald coefficient is calculated from the known sample size and the measured peak areas. The chromatograph is a Hewlett-Packard model 5750 equipped with a thermal conductivity cell detector. The carrier gas is helium. A 200 cm Porapak Q column is used for the separation.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Baker Chemical Co. Instrument grade, 99.99 percent. Used as received. (2) Hexane. Merck, Uvasol Spektroskopie grade. Impurities which give the same retention time as the gas are removed before the experiment by adsorption or distillation. ESTIMATED ERROR: $\delta L/L = \pm 0.05$ REFERENCES:

* vapor pressure of solid CO ₂ from ref. (1).																																																																							
AUXILIARY INFORMATION																																																																							
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																																																																						
The solubility of solid carbon dioxide was measured as described earlier (2). The components were introduced into the glass cell and 1 to 2 hr allowed for equilibrium to be reached. Samples of liquid were withdrawn at various temperatures from the glass equilibrium cell for analysis by gas chromatography. Alternatively the equilibrium temperatures of mixtures of known composition were measured. Temperatures were controlled by an air bath cooled by liquid nitrogen and measured by a calibrated platinum resistance thermometer. Pressures were measured by a calibrated Heise gage.	1. Coleman Instrument grade obtained from Matheson Gas Products. Analysis showed that the purity was better than 99.9%																																																																						
	2. Supplied by Phillips Petroleum Co. Analysis showed that the purity was better than 99.9%

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
The apparatus was described in an earlier paper (1). Deaerated solvent slowly flowed down a spiral tube in contact with the gas under test. The gas was maintained at constant pressure close to barometric. The rate of absorption of gas was measured by the rate of decrease of volume of gas. The concentration of gas in the liquid could then be calculated from the rate of flow of liquid.	1. Coleman Instrument Grade; minimum purity 99.99%.		
	2. Supplied by Canadian Laboratory Supplies; minimum purity 99.0 mol%.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		(1) Carbon dioxide. Air Products and Chemicals, Inc. Minimum mole per cent purity stated to be 99.8. (2) Octane. Phillips Petroleum Co. 99 mole per cent, distilled, density at 298.15 K, ρ/g cm ⁻³ 0.6988.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:	
The apparatus consists of a gas measuring buret, an absorption pipet, and a reservoir for the solvent. The buret is thermostated at 25°C, the pipet at any temperature from 5 to 30°C. The pipet contains an iron bar in glass for magnetic stirring. The pure solvent is degassed by freezing with liquid nitrogen, evacuating, then boiling with a heat lamp. The degassing process is repeated three times. The solvent is flowed into the pipet where it is again boiled for final degassing. Manipulation of the apparatus is such that the solvent never comes in contact with stopcock grease. The liquid in the pipet is sealed off by mercury. Its volume is the difference between the capacity of the pipet and the volume of mercury that confines it. Gas is admitted into the pipet. Its exact amount is determined by P-V measurements in the buret before and after introduction of the gas into the pipet. The stirrer is set in motion. Equilibrium is attained within 24 hours.			(1) Carbon dioxide. Western Gas Inc. Gas passed through a cold trap.	
			(2) Isooctane. Source not given. Distilled, purity checked by ultraviolet absorbance.	
			ESTIMATED ERROR:	
			δ T/K = 0.02 δ x ₁ /x ₁ = 0.003

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed. * Calculated by compiler assuming a linear function of P_{CO_2} vs x_{CO_2} , i.e., x_{CO_2} (1 atm) = $1/^H_{\text{CO}_2}$.																
AUXILIARY INFORMATION																
METHOD/APPARATUS/PROCEDURE: A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.	SOURCE AND PURITY OF MATERIALS: (1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent. ESTIMATED ERROR: $\delta T/K = \pm 0.1$; $\delta H/\text{atm} = \pm 6\%$ (estimated by compiler). REFERENCES:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
The solubility of carbon dioxide in eicosane was measured at four temperatures at pressures from 992 to 5063 kPa. Apparatus and procedure are described in an earlier paper (1). Gas was passed through the liquid in a thermostatted cell until saturation was achieved. Samples of solution were then withdrawn. The volume of the gas evolved when the pressure was reduced was measured and the eicosane weighed when it had cooled and solidified. The fugacity, <i>f</i> , of the carbon dioxide at various pressures was estimated by the method described by Lee and Kesler (2). The variation of ln(<i>f</i> / <i>x</i>) with pressure was linear to within a deviation of less than 0.8%. The value of <i>f</i> / <i>x</i> at zero pressure was taken to be the limiting value of the Henry's law constant.	1. Supplied by Matheson Gas Products. Minimum purity 99.8% 2. Supplied by Alfa Products, Morton Thiokol Inc. Minimum purity 99%. Gas chromatographic analysis showed no thermal degradation after the solubility measurements were carried out.

<p>The authors found that, at mole fractions of carbon dioxide less than 0.45, the variation in mole fraction solubilities with variation in pressure could be represented by the Krichevsky-Kasarnovsky equation (1) in the form:</p> $\ln(f_{\text{CO}_2}/x_{\text{CO}_2}) = \ln H + (\bar{V}_{\text{CO}_2}^\infty/RT)(P_b - P_{\text{hc}})$ <p>where f_{CO_2} = fugacity of CO₂ in the mixture H = Henry's constant $\bar{V}_{\text{CO}_2}^\infty$ = partial molar volume at infinite dilution of CO₂ in the liquid phase P_b = bubble point pressure P_{hc} = hydrocarbon vapor pressure</p> <p>The authors found values of H by plotting $\ln(f_{\text{CO}_2}/x_{\text{CO}_2})$ against P_b and extrapolating to zero pressure. Values of $\bar{V}_{\text{CO}_2}^\infty$ were found from the slope of the line.</p> <p>* calculated by the compiler from values of H and of $\bar{V}_{\text{CO}_2}^\infty$ given in the paper</p>				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The authors used a static equilibrium cell capable of handling solvents which were solid at room temperature. Bubble point pressures for various quantities of CO ₂ were found by decreasing the volume of the mixture and observing the break in the volume-pressure curve as the system changed from two phase to one phase. Mole fraction solubilities of CO ₂ for various pressures are given in the paper.		1. Supplied by Linde Speciality Gases; purity stated to be 99.99 mol%		
		2. Supplied by Alfa Products; purity stated to be 99 mol%		
		ESTIMATED ERROR;		
		See above.

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:										
Measurements on the vapor-liquid equilibria for the carbon dioxide-cyclopentane system were made at 310.9 K, 318.2 K and 333.2 K and total pressures to a maximum of 8263 kPa. The measurements reported above were the only ones at a pressure below 200 kPa. The apparatus and procedure were similar to that used previously by one of the authors (1). Mixtures were analysed by gas chromatography.	1. Research grade (99.99%) supplied by the Linde Division of Union Carbide. 2. Supplied by Aldrich; purified by distillation under nitrogen with only the middle 50% cut used.

¹ Mole fraction solubility values adjusted to a gas partial pressure of 101.325 kPa (1 atm) by the compiler.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: A calibrated all-glass combined manometer and bulb was enclosed in an air thermostat and shaken until equilibrium. Mercury was used for calibration and as confining liquid. The solvent was degassed in the apparatus. The absorbed volume of gas is calculated from the initial and final amounts, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. The mole fraction solubility values are at 1 atm assuming Henry's law is obeyed. Details of the apparatus and procedure are given in ref. 1 and 2.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Prepared from potassium bicarbonate (analytical reagent) and concentrated sulfuric acid. 99.9 per cent CO ₂ . (2) Cyclohexane. Purified by fractional freezing, dried, and distilled. AUXILIARY INFORMATION									
METHOD/APPARATUS/PROCEDURE: The apparatus consists of an all-glass buret system and a two bulb absorption vessel. A magnetic pump forces solvent from the lower bulb over the wall of the upper bulb which contains the gas. The solvent flow back to the lower bulb. Pumping is continued until there is no further pressure change. The amount of gas absorbed is calculated from the initial and final gas pressure.	SOURCE AND PURITY OF MATERIALS: No information. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).		(1) Carbon dioxide. Matheson Co., Inc. Research grade. Minimum volume percent purity is 99.995.	
Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns.		(2) Cyclohexane. Phillips Petroleum Co. Pure Grade. Distilled.	
Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		ESTIMATED ERROR:

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																
Apparatus able to withstand pressures to 20 MPa was used to determine phase equilibria by the bubble point method. Henry's constants at zero pressure were obtained from the experimental data by using the method described by Prausnitz and Chueh (1)	1. Supplied by Showa Tansan Industry Co., Ltd; purity better than 99.9% 2. Supplied by Wako Pure Chem. Co., Ltd.; purity better than 99.8%																
	ESTIMATED ERROR:																
	δT/K = ±0.01 δP/kPa = ±0.1 (authors)																
	REFERENCES:

COMPONENTS:		ORIGINAL MEASUREMENTS:
1. Carbon dioxide; CO ₂ ; [124-38-9] 2. Alicyclics or 1-Tetradecene		Luhring, P.; Schumpe, A. J. Chem. Eng. Data, 1989, 34, 250-252.
VARIABLES:		PREPARED BY:
T/K = 293.2		C.L. Young
EXPERIMENTAL VALUES:		
T/K	Henry's Constant* / (Pa m ³ /mol ⁻¹)	Mole fraction of CO ₂ at 1 atm partial pressure [†]
Cyclohexane; C ₆ H ₁₂ ; [110-82-7]		
293.2	1414	0.007746
Tetrahydronaphthalene, (tetralin); C ₁₀ H ₁₂ ; [119-64-2]		
293.2	1610	0.008576
Decahydronaphthalene, (decalin); C ₁₀ H ₁₈ ; [91-17-8]		
293.2	2001	0.007897
1-Tetradecene; C ₁₄ H ₂₈ ; [1120-36-1]		
293.2	1551	0.001654
* referred to as Henry's constant in source but appears to be usual Henry's constant multiplied by molar volume. † calculated by compiler using density data taken from ref.(1).		
AUXILIARY INFORMATION		
METHOD/APPARATUS/PROCEDURE		SOURCE AND PURITY OF MATERIALS:
Little information given in source. Method consisted of equilibrating known amounts of degassed liquid and gas and measuring the change in pressure. Equilibration was reached in 3 to 6 minutes. Some details given in ref.(2).		Obtained from Merck at the highest available purity. No other details given.
		ESTIMATED ERROR: δT/K = ± 0.1 (authors) δx/x = ± 0.01 to 0.15 (compiler)

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																									
A cylindrical glass container of approximately 15 cm ³ volume is partly filled with solvent and closed with a half-hole septum. An amount of the gaseous solute is added to the container. The closed container is shaken for 30 minutes. Samples of both the vapor and liquid phases are taken in a calibrated syringes. The samples are injected into a gas chromatograph. The Ostwald coefficient is calculated from the known sample size and the measured peak areas.		(1) Carbon dioxide. Baker Chemical Co. Instrument grade, 99.99 percent. Used as received.																									
		(2) Cyclohexane. Merck and Co. Uvasol spektroskopie grade. Methylcyclohexane. Fluka. UV-Spektroskopie grade. Impurities which gave same retention times as the gas were removed by absorption or distillation. Otherwise used as rcvd.																									
The chromatograph is a Hewlett-Packard model 5750 equipped with a thermal conductivity cell detector. The carrier gas is helium. A 200 cm Porapak column is used for the separation.		ESTIMATED ERROR:																									
		δ L/L = ± 0.05

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Either Matheson Co., Inc. or Air Products and Chemicals, Inc. Purest grade available, minimum purity greater than 99 mole per cent. (2) Methylcyclohexane. Phillips Petroleum Co. Pure Grade. Distilled.

AUXILIARY INFORMATION												
METHOD/APPARATUS/PROCEDURE: A cylindrical glass container of approximately 15 cm ³ volume is partly filled with solvent and closed with a half-hole septum. An amount of the gaseous solute is added to the container. The closed container is shaken for 30 minutes. Samples of both the vapor and liquid phases are taken in a calibrated syringes. The samples are injected into a gas chromatograph. The Ostwald coefficient is calculated from the known sample size and the measured peak areas. The chromatograph is a Hewlett-Packard model 5750 equipped with a thermal conductivity cell detector. The carrier gas is helium. A 200 cm Porapak column is used for the separation.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Baker Chemical Co. Instrument grade, 99.99 percent. Used as received. (2) 1,1'-Bicyclohexyl. Fluka. purum grade. Impurities which give the same retention time as the gas are removed before the experiment by adsorption or distillation. ESTIMATED ERROR: $\delta L/L = \pm 0.05$ REFERENCES:

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																																														
The data given above were obtained during studies of the systems to higher pressures over the whole of each composition range. The apparatus has been described previously (1). The components were charged into a glass-windowed equilibrium cell. A magnetic piston pump recirculated vapor, removed it from the top of the liquid and reintroduced it into the bottom of the liquid. After equilibrium was reached (c. 0.5 h) samples of the gas phase and of the liquid phase were analysed by gas chromatography.	1. Purity at least 99.8%

* calculated by the compiler from vapor pressure equations for solid CO ₂ given in the literature; 130-145 K ref.(1); 150-180 K ref.(2).						
AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:				
The experimental method is described in ref. (3). Vapor pressures of saturated solutions of carbon dioxide with excess solid in various mixtures of ethane and ethene were measured over temperature ranges with a five junction copper constantin thermocouple. The vapor pressures of solutions of carbon dioxide of known composition were then measured at the point of appearance and of disappearance of the solid carbon dioxide. The corresponding temperatures were then found from the relationship between temperature and vapor pressure which had been established in the first series of measurements.		Components were obtained from commercial sources and purified as described in ref. (3).

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:						
Gas chromatographic analysis of a saturated solution at barometric pressure. Henry's constants determined from formula $H = (p - p_o)\phi(m + 1)/m$ where p is the total pressure, p _o the vapor pressure of the solvent and φ is the fugacity coefficient of the gas. The mole ratio, m, is defined by $m = \frac{\text{Moles of carbon dioxide in gas phase}}{\text{Moles of carbon dioxide in liquid phase}}$	1. No details given. 2. Purity 99.06 mole per cent.						
	ESTIMATED ERROR: δT/K = ±0.25; δH/atm = ±3% (estimated by compiler).

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Aromatic Hydrocarbons 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in aromatic hydrocarbons</p> <p>Solubility in benzene at pressures below 200 kPa has been studied by at least ten groups (1-10). Limiting values of Henry's constant from high pressure data published by Kaminishi <i>et al.</i> (11) can also be used to estimate the mole fraction solubility at lower pressures. Values of mole fraction solubility at a partial pressure of 101.3 kPa from the available data are not very consistent. Values for 283.2 K range from 0.0107 to 0.01208 and values for 293.2 K range from 0.0091 to 0.0099 with a value of 0.0105 at 293.6 K. There is better agreement at other temperatures. Over the whole temperature range the values of mole fraction solubility at a partial pressure of 101.3 kPa, based on (1-10), fit the equation given below.</p> $\ln x_{\text{CO}_2} = -18.437 + 1296.5/(T/K) + 1.6511 \ln(T/K)$ <p>temperature range = 283.2-313.2 K standard deviation in x_{CO_2} = 0.00037</p> <p>At least ten groups (1,2,4,6,8,12-16) have measured solubility of carbon dioxide in methylbenzene at pressures below 200 kPa. There is, in general, good agreement between values for mole fraction solubility in this solvent at a partial pressure of 101.3 kPa. However the solubility at 193.2 K reported by Williams seems to be too low. Values of the mole fraction solubility at a partial pressure of 101.3 kPa from other measurements by Williams and by other workers fit the equation below.</p> $\ln x_{\text{CO}_2} = -13.921 + 1547.7/(T/K) + 0.72764 \ln(T/K)$ <p>temperature range = 203.2-316.2 K standard deviation in x_{CO_2} = 0.00128</p> <p>Three groups (1,9,17) measured solubility in 1,2-dimethylbenzene. Values of mole fraction solubility at a partial pressure of 101.3 kPa are consistent with each other and fit the equation below.</p> $\ln x_{\text{CO}_2} = -52.371 + 3066.3/(T/K) + 6.5757 \ln(T/K)$ <p>temperature range = 253.2-313.2 standard deviation in x_{CO_2} = 0.00016</p> <p>Six groups (1,4,6,8,9,17) measured solubility in 1,3-dimethylbenzene. Again there is good consistency between different sets of data. Values of mole fraction solubility fit the following equation</p> $\ln x_{\text{CO}_2} = -49.384 + 2960.3/(T/K) + 6.1263 \ln(T/K)$ <p>temperature range = 233.2-313.1 K standard deviation in x_{CO_2} = 0.00015</p> <p>Solubility in 1,4-dimethylbenzene was measured at 293.15 K by Rosenthal (9) and by Piskovsky and Lakomy (1). Byrne <i>et al.</i> (17) measured the solubility at 313.13 K, 298.12 K and three temperatures between 288 K and 289 K. Values of mole fraction solubility at a partial pressure of 101.3 kPa are consistent with each other but the temperature range is small in comparison with measurements of the solubility in the other two isomers of dimethylbenzene. These values fit the following equation</p> $\ln x_{\text{CO}_2} = -247.112 + 11816.1/(T/K) + 35.617 \ln(T/K)$ <p>temperature range = 288.2-313.1 standard deviation in x_{CO_2} = 0.00021</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Aromatic Hydrocarbons 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>						
<p>CRITICAL EVALUATION:</p> <p>Mole fraction solubilities at a partial pressure of 101.3 kPa at 293.15 K from smoothing equations for the three isomers are as follows:</p> <table> <tbody> <tr> <td>1,2-dimethylbenzene</td><td>0.0105</td></tr> <tr> <td>1,3-dimethylbenzene</td><td>0.0113</td></tr> <tr> <td>1,4-dimethylbenzene</td><td>0.0114</td></tr> </tbody> </table> <p>Bratzler <i>et al.</i> (18) have published the Bunsen coefficient for a mixture of isomers of dimethylbenzene at 293 K. The corresponding mole fraction solubility at a partial pressure of 101.3 kPa is 0.011. The mole fraction solubility in a mixture of isomers at 293.15 K and 101.3 kPa from measurements by Vitovec (19) is 0.0109. These values are consistent with the values for the individual isomers.</p> <p>Solubility in ethylbenzene has been measured by Piskovsky and Lakomy (1) from 198.2 K to 293.2 K and by Luhning and Schumpe (8) at 293.2 K. Piskovsky's measurements are self consistent. The mole fraction solubility at 293.2 K and a partial pressure of 101.3 kPa from Piskovsky's measurements is 0.0108 compared with Luhning's value of 0.01022. Values from the two sources fit the equation</p> $\ln x_{\text{CO}_2} = -52.108 + 3033.9/(T/K) + 6.5525 \ln(T/K)$ <p>temperature range = 198.2-293.2 K standard deviation in x_{CO_2} = 0.00049</p> <p>Just (6) reported the solubility of carbon dioxide in (1-methylethyl)-benzene at temperatures from 288.15 K to 298.15 K. Values of mole fraction solubility are close to those for ethylbenzene but no other data on this solvent are available for comparison.</p> <p>Luhning and Schumpe (8) reported a Henry's constant for solubility in 1,2,4-trimethylbenzene at 293.2 K. This corresponds to a mole fraction solubility of 0.01125 at a partial pressure of 101.3 kPa which is close to values for solubility in the dimethylbenzenes under these conditions. No other measurements of the solubility in this solvent are available for comparison.</p> <p>Tremper and Prausnitz (20) have published Henry's constants for 1,1'-methylenebisbenzene for 300 K to 475 K. Horvath <i>et al.</i> (4) published a Henry's constant for 300 K of 124 atm. This is very close to Tremper's value of 123 atm. Mole fraction solubilities for a partial pressure of 101.3 kPa calculated from Henry's constants in the two papers fit the equation below.</p> $\ln x_{\text{CO}_2} = -37.246 + 2368.7/(T/K) + 4.3008 \ln(T/K)$ <p>temperature range = 300-475 K standard deviation in x_{CO_2} = 6.2×10^{-5}</p> <p>Measurements by Glazunova (21) show that the mole fraction solubility in 1,1'-methylenebis(methylbenzene) in the temperature range 293 K to 393 K is greater than that in 1,1'-methylenebisbenzene under the same conditions. Mole fraction solubility in methylbenzene is greater than that in benzene under similar conditions. No other measurements of the solubility in 1,1'-methylenebis(methylbenzene) are available for comparison. Glazunova's measurements fit the equation given below. This equation can only be accepted on a tentative basis.</p> $\ln x_{\text{CO}_2} = -8.3777 + 1156.2/(T/K)$ <p>temperature range = 293-393 K standard deviation in x_{CO_2} = 0.00019</p>		1,2-dimethylbenzene	0.0105	1,3-dimethylbenzene	0.0113	1,4-dimethylbenzene	0.0114
1,2-dimethylbenzene	0.0105						
1,3-dimethylbenzene	0.0113						
1,4-dimethylbenzene	0.0114						

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Aromatic Hydrocarbons 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility of carbon dioxide in (1-methylethyl)-1,1'-biphenyl has been measured to high pressures at 293.2 K, 373.2 K and 473.2 K by Bogdanov (22). The mole fraction solubility at 293.2 K and a partial pressure of 101.3 kPa is approximately 0.0113. No measurements by other authors are available for comparison.</p> <p>Horvath <i>et al.</i> (4) have found a Henry's constant of 151 atm for dissolution in 1-methylnaphthalene at 300 K. Chai and Paulaitis (23) reported Henry's constants at temperatures from 298.6 K to 330.2 K. The interpolated value at 300 K is 151.4, close to the value reported by Horvath. Mole fraction solubilities calculated from Henry's constants published by the two groups fit the equation</p> $\ln x_{\text{CO}_2} = -1.8516 + 759.73/(T/K) - 0.99967 \ln(T/K)$ <p>temperature range = 298.6-311.0 standard deviation in $x_{\text{CO}_2} = 3.4 \times 10^{-5}$</p> <p>A selection of mole fraction solubilities in aromatic hydrocarbons is shown in Table 1 and Fig 1.</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. CRITICAL EVALUATION:

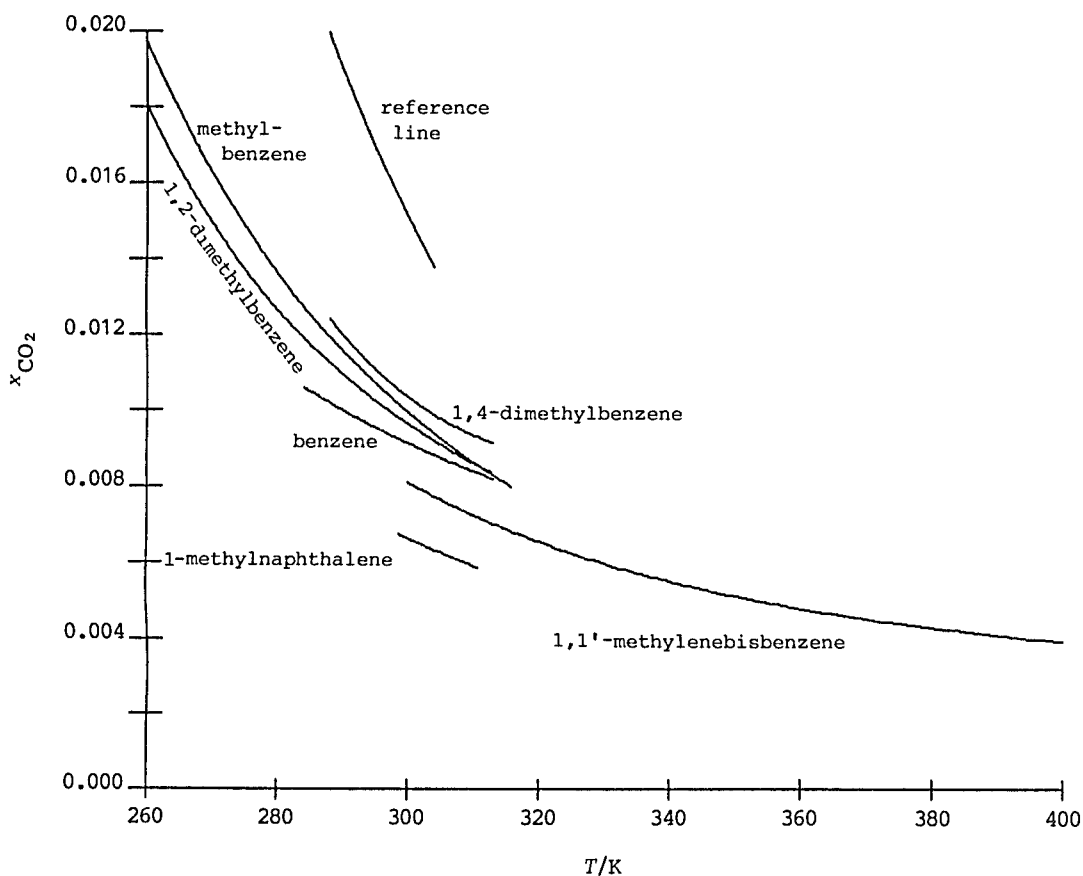

Fig. 1 Mole fraction solubility of carbon dioxide in various aromatic hydrocarbons at a partial pressure of gas of 101.3 kPa.

The curves showing the variation of solubility with temperature correspond to equations derived by the evaluator.

A reference line corresponding to values from the Raoult's law equation is also shown.

AUXILIARY INFORMATION																															
METHOD/APPARATUS/PROCEDURE: A calibrated all-glass combined manometer and bulb was enclosed in an air thermostat and shaken until equilibrium. Mercury was used for calibration and as confining liquid. The solvent was degassed in the apparatus. The absorbed volume of gas is calculated from the initial and final amounts, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. The mole fraction solubility values are at 1 atm assuming Henry's law is obeyed. Details of the apparatus and procedure are given in ref. 1 and 2.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid nitrogen trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The de- gassed solvent is passed in a thin film down a glass helical tube con- taining solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed. * Values of Henry's constant based upon measurements made in the pressure range 101-1621 kPa and calculated by a graphical method from the relationship						
$RT \ln(f_2/x_2) = RT \ln H + \int_0^P \bar{V}_2 dP - Ax_2$						
where f ₂ is the fugacity of the carbon dioxide at pressure P						
\bar{V}_2 is the partial molar volume of carbon dioxide at infinite dilution						
H is equal to the limiting value of P ₂ /x ₂ at P ₂ =0; A is a constant.						
** Values of Henry's constant based upon measurements of the solubility of carbon dioxide at a partial pressure of 101.3 kPa.						
† calculated by the compiler and equal to the reciprocal of H**/atm						
§ calculated by the compiler						
‡ the authors used data for methanol which they had published earlier (1).						
AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:			
A static method was used. A glass (low pressure) section of the apparatus was connected to a high pressure section made of metal. Carbon dioxide in the low pressure section was allowed to condense in a cooled metal bulb in the high pressure section. The quantity of gas collected was found from pressure changes in the glass section. The valve connecting the two section was then closed and the condensed gas allowed to evaporate to generate the required pressure and to come in contact with the solvent under test which was held in an absorption cell in a thermostat bath. The cell was stirred magnetically. The quantity of unabsorbed gas when equilibrium was reached was calculated from the final pressure and volume of the gas in the high pressure section. The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).		(1) Carbon dioxide. Either Matheson Co., Inc. or Air Products and Chemicals, Inc. Purest grade available, minimum purity greater than 99 mole per cent.	
Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns.		(2) Methylbenzene. Phillips Petroleum. Pure Grade. Distilled.	
Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		ESTIMATED ERROR:

AUXILIARY INFORMATION																																							
METHOD/APPARATUS/PROCEDURE: The prepared solvent solution was charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring burette in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and volume of gas used. Solubilities were measured at pressures above and below atmospheric.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Source and purity not given. An aqueous "soda" solution absorbed 99.8% of the gas. (2) Aromatic hydrocarbons.

298.15	10.92
303.15	10.25
313.15	9.08

| **AUXILIARY INFORMATION** | | | |
| **METHOD/APPARATUS/PROCEDURE:** The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed. | | **SOURCE AND PURITY OF MATERIALS:** (1) Carbon dioxide. Either Air Products & Chemicals, Inc., or Matheson Co., Inc. 99 mol per cent or better. (2) 1,4-Dimethylbenzene. Phillips Petroleum Co. Pure grade. Used as received. **ESTIMATED ERROR:** $\delta T/K = 0.01$ $\delta P/mmHg = 0.5$ $\delta x_1/x_1 = 0.001$ **REFERENCES:** 1. Morrison, T. J.; Billett, F. *J. Chem. Soc.* 1948, 2033. 2. <p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in alcohols.</p> <p>Measurements by Makranczy <i>et al.</i>(1) indicate that mole fraction solubilities in straight chain primary alkanols at 298.2 K and a partial pressure of carbon dioxide of 101.3 kPa increase linearly with carbon number from methanol to dodecanol. This trend has not been confirmed by other workers. In cases where comparison is possible, the higher the carbon number the greater the divergence of Makranczy's data from other data which are available (Fig. 1).</p> <p>Shenderei <i>et al.</i>(2) published values of the solubility in methanol from 13.33 kPa to 101.3 kPa at 194.5 K to 273.2 K. These measurements show linear variation of mole fraction solubility with pressure at every temperature even to a value of 0.25 at 194.5 K and 93.33 kPa. Linear variation to such a high value appears to be inconsistent with the measurements at high pressures and higher temperatures by Krichevskii and Lebedeva (3). These authors found that mole fraction solubility curves at constant temperature were convex towards the pressure axis.</p> <p>Values of the mole fraction solubility at a partial pressure of 101.3 kPa may be found from published data for 202.6 K to 307.2 K (1-14). Values for 293.2 range from 0.00602 (6) to 0.00719 (7) and for 298.2 from 0.00568 (6) to 0.00635 (10). The evaluator recommends the smoothing equation for mole fraction solubilities at a partial pressure of 101.3 kPa which is given below. This is based upon ten of the papers (2-4,7-10,13,14).</p> $\ln x_{\text{CO}_2} = -49.919 + 3484.7/(T/K) + 5.8265 \ln(T/K)$ <p>temperature range = 202.6-323.0 K standard deviation in x_{CO_2} = 0.00139</p> <p>Solubility in ethanol at a partial pressure of 101.3 kPa in the temperature range 212.7 K to 333.4 K has been published in at least nine papers (1,2,4,6,10-12,15,16). Shenderei <i>et al.</i>(2) measured the solubility in ethanol from 13.33 kPa to 101.3 kPa at 212.7 K to 248.0 K. Data are self consistent and there is no reason to doubt the reliability. The value of the mole fraction solubility at 298.15 ranges from 0.00624 (Takahashi <i>et al.</i>(16)) to 0.00728 (Won <i>et al.</i>(11)). Takahashi calculated solubility from the rate of absorption of gas. The method is an interesting one but is likely to be less reliable than conventional methods. Kunerth's measurements (6) from 291.2 K to 307.2 K may again be too low. The evaluator considers that measurements by Cargill and MacPhee (15) to be the most reliable in the temperature range 277.9 K to 333.4 K. These measurements agree with the solubility at 298.15 K measured by Won <i>et al.</i> (11) and are close to measurements by Kosakewitsch (12), Makranczy <i>et al.</i>(1) and by Luhring and Schumpe (4). The only measurements below 277 K are by Shenderei <i>et al.</i>(2). These appear to be consistent with measurements at higher temperatures and can be tentatively recommended.</p> <p>The following equation for mole fraction solubility at a partial pressure of 101.3 kPa is based upon measurements by Cargill and MacPhee and by Won <i>et al.</i></p> $\ln x_{\text{CO}_2} = -22.278 + 2027.1/(T/K) + 1.8521 \ln(T/K)$ <p>temperature range = 277.9-333.4 K standard deviation in x_{CO_2} = 1.56×10^{-5}</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>

CRITICAL EVALUATION:

Fig. 1 Values from various sources of the mole fraction solubility of carbon dioxide in straight chain primary alkanols at 298.15 K and a partial pressure of gas of 101.3 kPa.

- from the smoothing equations given by the evaluator
- X Makranczy *et al.* (1)
- ▲ Dim *et al.* (21)
- △ Wilcock *et al.* (20)

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>The equation given below for mole fraction solubility at a partial pressure of 101.3 kPa is based upon measurements by Cargill and MacPhee, by Won <i>et al.</i>, and by Shenderei <i>et al.</i></p> $\ln x_{\text{CO}_2} = -56.735 + 3560.0/(T/K) + 6.9952 \ln(T/K)$ <p>temperature range = 212.7-333.4 K standard deviation in x_{CO_2} = 0.00038</p> <p>Solubility in 1-propanol was measured by Shenderei <i>et al.</i>(2) from 13.3 kPa to 101.3 kPa at 212.7 K to 248.0 K. There is no reason to doubt the reliability but no similar measurements in this temperature and pressure range are available for comparison. Tokunaga (17) reported Ostwald coefficients and Henry's constants measured at or close to 101.3 kPa from 283.2 K to 313.2 K. Mole fraction solubility at 298.2 K is available from work by Makranczy <i>et al.</i>(1), Takahashi <i>et al.</i>(16) and Just (10). These values range from 0.00470 (Takahashi) to 0.00782 (Makranczy). The interpolated value from Tokunaga's work is 0.00679. Takahashi used a method which depended upon measuring absorption rates and the value is much too low. Measurements by Makranczy <i>et al.</i> for primary alkanols show a trend which differs from that shown by other measurements. The equation for mole fraction solubility given below and based upon measurements by Shenderei <i>et al.</i> and by Tokunaga <i>et al.</i> is recommended on a provisional basis. i.e.</p> $\ln x_{\text{CO}_2} = -52.708 + 3312.9/(T/K) + 6.4248 \ln(T/K)$ <p>temperature range = 212.7-313.2 K standard deviation in x_{CO_2} = 0.00028</p> <p>Solubility in 2-propanol was also measured by Shenderei <i>et al.</i>(2) from 13.3 kPa to 101.3 kPa at 212.7 K to 248.0 K. Again there is no reason to doubt the reliability of these measurements but no other measurements in this temperature and pressure range are available for comparison. Tokunaga (17) measured the solubility in this solvent at about 101.3 kPa in the temperature range 283.2 K to 313.2 K. A measurement at 293.2 K by Luhning and Schumpe (4) corresponds to a mole fraction solubility of 0.00720. The value from Tokunaga's work is 0.00685.</p> <p>An equation for mole fraction solubility at a partial pressure of 101.3 kPa which is based upon measurements by Shenderei <i>et al.</i> and by Tokunaga is recommended on a provisional basis. i.e.</p> $\ln x_{\text{CO}_2} = -83.277 + 4450.3/(T/K) + 11.112 \ln(T/K)$ <p>temperature range = 212.7-313.2 K standard deviation in x_{CO_2} = 0.00032</p> <p>Shenderei <i>et al.</i>(2) measured solubility in 1-butanol from 13.3 kPa to 101.3 kPa at 212.7 K to 248.0 K. The data is self consistent but no other measurements under these conditions are available for comparison. The solubility reported by Makranczy <i>et al.</i>(1) corresponds to a mole fraction of 0.008832 at 298.15 K and a partial pressure of 101.3 kPa. Luhning and Schumpe's data (4) correspond to a mole fraction solubility of 0.00781 at 293.15 K and a partial pressure of 101.3 kPa. This latter value is not compatible with Makranczy's data. The evaluator considers that Luhning's value is more likely to be reliable. The following smoothing equation based upon measurements by Shenderei <i>et al.</i> and by Luhning and Schumpe is</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>recommended on a tentative basis until further measurements on the system are available.</p> $\ln x_{\text{CO}_2} = -52.475 + 3272.5/(T/K) + 6.4171 \ln(T/K)$ <p>temperature range = 212.7-293.2 K standard deviation in x_{CO_2} = 0.00038</p> <p>Shenderei <i>et al.</i>(2) measured the solubility in 2-methyl-1-propanol from 13.3 kPa to 101.3 kPa at 212.7 K to 248.0 K. The data is self consistent but no other measurements at these temperatures and pressures are available for comparison. Battino <i>et al.</i>(18) measured solubility at 101.3 kPa from 274.0 K to 328.0 K. Battino's measurements are in satisfactory agreement with earlier measurements by Just (10) from 288.2 K to 298.2 K. Takahashi <i>et al.</i>(16) estimated the solubility from absorption studies. Their data correspond to a mole fraction solubility of 0.00628 at 298.2 compared with a value of 0.00697 from Battino and 0.0698 from Just.</p> <p>The following equation based upon data from Battino <i>et al.</i> and from Just is recommended as likely to be reliable.</p> $\ln x_{\text{CO}_2} = -7.5561 + 1195.7/(T/K) - 0.24941 \ln(T/K)$ <p>temperature range = 274.0-328.0 K standard deviation in x_{CO_2} = 9.7×10^{-5}</p> <p>The following equation based upon data from Shenderei <i>et al.</i>, Battino <i>et al.</i> and from Just can be accepted on a tentative basis</p> $\ln x_{\text{CO}_2} = -75.542 + 4061.4/(T/K) + 9.9928 \ln(T/K)$ <p>temperature range = 212.7-328.0 standard deviation in x_{CO_2} = 0.00055</p> <p>Shenderei <i>et al.</i>(2) measured solubility in 2-butanol from 13.3 kPa to 101.3 kPa at 211.7 K to 248.0 K. The data is self consistent. No other measurements of solubility of carbon dioxide in this solvent are available for comparison.</p> <p>Solubility in 1-pentanol has been measured by Just (10) in the range 288.2 K to 298.2 K and by Pedrosa <i>et al.</i>(19) in the range 288.2 K to 318.2 K. There is good agreement between the two sets of measurements. A smoothing equation for mole fraction solubility at a partial pressure of 101.3 kPa based on these two sets of measurements is given below. Solubility reported by Makranczy <i>et al.</i>(1) for 298.15 K seems to be too high.</p> $\ln x_{\text{CO}_2} = -119.31 + 6103.7/(T/K) + 16.501 \ln(T/K)$ <p>temperature range = 288.3-318.2 K standard deviation in x_{CO_2} = 5.9×10^{-5}</p> <p>Kunerth (6) published values of the solubility in 3-methyl-1-butanol at 101.3 kPa for 293.2 K to 307.2 K. These are close to values for 1-pentanol discussed above. A smoothing equation for mole fraction solubility at a partial pressure of 101.3 kPa is given below. It should be noted that values of solubility in methanol and in ethanol published in</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>the same paper are slightly low in comparison with values measured more recently.</p> $\ln x_{\text{CO}_2} = 9.5281 + 390.83/(T/K) - 2.7484 \ln(T/K)$ <p>temperature range = 293.2-307.2 K standard deviation in $x_{\text{CO}_2} = 3.6 \times 10^{-5}$</p> <p>Solubilities in 1-hexanol and 1-heptanol have been published by Makranczy <i>et al.</i>(1). Solubility in 1-heptanol has also been measured by Dim <i>et al.</i>(21). Values from both sources are high compared with solubilities in other alkanols (Fig 1).</p> <p>The solubility in 1-octanol at a partial pressure of 101.3 kPa was measured by Wilcock <i>et al.</i>(20) from 282.7 K to 313.6 K. Solubilities at 298.2 K reported by Makranczy <i>et al.</i>(1) and by Dim <i>et al.</i>(21) are high in comparison with Wilcock's measurements. Takahashi <i>et al.</i>(16) published a value at 298 K from a study of the rate of absorption of gas. This value is unlikely to be reliable and is low relative to Wilcock's values. Measurements by Wilcock <i>et al.</i> are recommended on a provisional basis.</p> <p>The solubility in 1-nonanol has been published by Macranczy <i>et al.</i>(1). (Fig 1)</p> <p>Wilcock <i>et al.</i>(20) published values of solubility in 1-decanol at 284.0 K to 313.5 K. and a partial pressure of 101.3 kPa. The data can be recommended on a provisional basis. Macranczy <i>et al.</i>(1) published a value for 298.2 K which is very high in comparison with Wilcock's value (Fig 1).</p> <p>Makranczy <i>et al.</i>(1) measured solubility in 1-undecanol and 1-dodecanol at 298.2 K (Fig 1).</p> <p>Solubility in an equimolar mixture of 1-decanol and 1-dodecanol was measured by Luther and Hiemenz (22) from 293.2 K to 355.2 K. The mole fraction solubility at 293.2 K and a partial pressure of 101.3 kPa is given as 0.0107 compared with a value for the solubility in pure 1-decanol of 0.0106 from measurements by Wilcock <i>et al.</i>(20).</p> <p>The solubility in cyclohexanol was measured by Begley <i>et al.</i>(23) at a partial pressure of 101.3 kPa from 298.3 K to 321.0 K. The value of the mole fraction solubility at 298.3 K is 0.00442 which may be compared with a value of 0.00286 from much earlier measurements by Cauquil (24). Begley's measurements are likely to be the more reliable. It is clear that mole fraction solubility in cyclohexanol is much lower than solubility in 1-hexanol or in cyclohexane under similar conditions.</p> <p>The solubility in benzenemethanol to high pressures was measured by Emel'yanova <i>et al.</i>(25) over the temperature range 323.2 K to 398.2 K. Solubility at a partial pressure of 101.3 kPa can be estimated from the data. Extrapolation to 298.2 K and a partial pressure of 101.3 kPa gives a value of the mole fraction solubility of about 0.0044. This is in contrast to the value of 0.00781 estimated from measurements of the limiting value of Henry's constant measured by gas-liquid chromatography and reported by Lenoir <i>et al.</i>(26). Surface adsorption can give erroneous values of Henry's constants measured by chromatography. Mole fraction solubility at a partial pressure of 101.3 kPa from Emel'yanova's measurements can be provisionally recommended in the absence of measurements conducted at barometric pressure.</p> <p>Mole fraction solubilities in dihydric alkanols are lower than in monohydric alkanols. The mole fraction solubility at a partial pressure of 101.3 kPa in 1,2-ethanediol from work by Byeseda <i>et al.</i>(27) is 0.0031 at 297.1 K and from work by Hayduk and Malik (29) is 0.0022 at 298.2 K.</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> Carbon dioxide; CO₂; [124-38-9] Alcohols 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>The value at 298.2 K from chromatographic measurements by Lenoir <i>et al.</i>(26) is 0.00382. The corresponding value for ethanol is 0.00725. Further work on the system is required before a solubility value can be recommended</p> <p>Semenova <i>et al.</i>(28) measured the solubility in butane-1,4-diol to high pressures at 323.2 K to 398.2 K. Data can be extrapolated to 101.3 kPa. Further extrapolation to 298.2 K and 101.3 kPa indicates a mole fraction solubility of about 0.00395 compared with a value of 0.00717 for 1-butanol. Semenova's data may be accepted on a provisional basis until there is confirmation by other workers.</p> <p>Just (10) measured solubility in 1,2,3-propanetriol at 298.2 K. Measurements indicate a mole fraction solubility of 0.0000903 at 101.3 kPa. Such a low value must be treated with suspicion until it has been confirmed by other workers.</p> <p>A selection of mole fraction solubilities in alcohols is given in Table 1.</p> <p>REFERENCES</p> <ol style="list-style-type: none"> Makranczy, J.; Rusz, L.; Balog-Megyery, K. <i>Hung. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
<p>The method is based upon that described by McDaniel (1). The apparatus consisted of a gas buret attached to a levelling tube containing mercury and to the absorption cell containing the solvent under test. The volume of gas absorbed by a measured volume of liquid was measured at a total pressure equal to barometric pressure. The mercury in the gas buret was covered with a layer of solvent so that the gas in the buret was saturated with solvent vapor. Buret and absorption cell were surrounded by heating wire and water jackets fitted with thermometers.</p>		1. produced by heating NaHCO ₃ ; dried with CaCl ₂ ; frozen in liquid air and volatile impurities pumped away; passed over P ₂ O ₅ .	
		2. commercial sample; purity attested by boiling point and density.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:	
Carbon dioxide was bubbled through the solvent for two to four days. A portion of the saturated solution was then added to CO ₂ -free water containing a measured quantity of sodium hydroxide. The mixture of sodium hydroxide and carbonate was then titrated against hydrochloric acid using phenolphthalein as indicator.			1. Carbon dioxide was prepared by the action of hydrochloric acid on calcium carbonate. The gas was purified and dried by the usual methods.	
Solubilities were corrected to a partial pressure of carbon dioxide of 101.3 kPa.			2. Alcohols were said to be free of water.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The carbon dioxide solubility was determined by saturating the liquid phase in a gas bubbler immersed in an isothermal bath. The liquid phase carbon dioxide concentration was determined by using a standard wet chemistry technique (1). The partial pressure of the carbon dioxide over the liquid was calculated by subtracting the vapor pressure of the liquid from the measured total pressure.		(1) Carbon dioxide. No information.		
The diffusivity of carbon dioxide was measured. $10^9D/\text{m}^2 \text{ s}^{-1} = 8.37$		(2) Methanol. Source not given. The density, kinematic viscosity, and surface tension were measured and reported in the paper. Values are $\rho/\text{kg m}^{-3} = 786.6$, $10^6\nu/\text{m}^2 \text{ s}^{-1} = 0.695$, and $10^3\sigma/\text{N m}^{-1} = 22.2$.

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket. The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. The mole fraction and Ostwald coefficients were calculated by the compiler.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The carbon dioxide solubility was determined by saturating the liquid phase in a gas bubbler immersed in an isothermal bath. The liquid phase carbon dioxide concentration was determined by using a standard wet chemistry technique (1). The partial pressure of the carbon dioxide over the liquid was calculated by subtracting the vapor pressure of the liquid from the measured total pressure. The diffusivity of carbon dioxide was measured. 10 ⁹ C/m ² s ⁻¹ = 3.88.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. No information. (2) Ethanol. Source not given. The density, kinematic viscosity, and surface tension were measured and reported in the paper. Values are ρ/kg m ⁻³ = 785.0, 10 ⁶ ν/m ² s ⁻¹ = 1.400, and 10 ³ σ/N m ⁻¹ = 22.7.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: An indirect method (1) was used in which the absorption rate of carbon dioxide into the mixed solvent was measured as a function of time. It was assumed that the film-theory model of the gas absorption process applied. A plot of ln (absorption rate) vs. time is linear. The slope is a function of the diffusion coefficient and the intercept is a function of both the diffusion coefficient and the solubility. A diaphragm cell with interfacial area 5.81 cm ² and lower compartment volume for the liquid was 53.5 cm ³ . The diaphragm was Millipore Teflon of mean pore size 10.0 μm, thickness 125 ± 15 μm, and porosity 0.68. The liquid was stirred at a constant rate of 1.33 rotations s ⁻¹ . The solutions were prepared and then degassed by refluxing for five hours. Their compositions were determined by density or refractive index. The CO ₂ was presat. with solvent vap.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Source not identified. From cylinder. (2, 3) Ethanol and 1-Propanol. It was stated that the chemicals were of special grade. * calculated by the compiler					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
Solvents were refluxed for several hours to remove dissolved gases. a measured volume of the solvent was then transferred to an absorption chamber fitted with a magnetic stirrer and connected to a system of gas burets, vacuum line and mercury reservoir. A measured volume of the gas then came in contact with the liquid which was agitated until equilibrium was reached. The final volume of the gas was then measured.			1. super pure grade from Nippon Tansan Co. Ltd.; 98.96% pure.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).		(1) Carbon dioxide. The Matheson Co. Inc. Commercial grade stated to be better than 99 mol per cent.	
Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns.		(2) 2-Methyl-1-propanol. Fisher Co. Certified grade (99 mol per cent).	
Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		ESTIMATED ERROR:

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																														
Densities of the pure solvent were measured using a digital densitometer AP, model DMA 45 with temperatures controlled to 0.01 K with a Haake thermostat and measured to 0.01 K by a Digtec thermometer. The densitometer was first calibrated with distilled water.	1. from a cylinder; purity 99.5% 2. Merck p.a. grade was used without further purification apart from degasification by boiling.																														
The method and details of apparatus for measuring the absorption of gas are given in ref. (1). An Erlenmeyer flask connected to a pressure transducer was used. The transducer was first calibrated against a manometer containing dibutyl phthalate.	ESTIMATED ERROR:

METHOD/APPARATUS/PROCEDURE: The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed. VARIABLES:	PREPARED BY:			
T/K = 293.15-355.15 P/kPa = 0-80 kPa	P.G.T. Fogg			
EXPERIMENTAL VALUES:				
The solvent consisted of an equimolar mixture of 1-decanol and 1-dodecanol.				
T/K	Concentration of CO ₂ * /mol m ⁻³ liquid gas	Ostwald coeff. L	Henry's law constant /atm /kPa**	Mole fraction solubility at 101.3 kPa
293.15	7.56 5.61	1.35	93.7±1.9 9490±190	0.0107
314.15	5.43 5.25	1.03		
334.65	4.30 5.00	0.850		
355.15	3.48 4.75	0.733		
At 293.15 K the mole fraction solubility was shown to be proportional to the partial pressure of carbon dioxide to a pressure of at least 600 Torr (80 kPa).				
* concentrations correspond to partial pressures of carbon dioxide of about 13 kPa.				
** calculated by the compiler.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:			
A spectroscopic method was used. The gas and solution under test was circulated through cuvettes. The concentration of carbon dioxide in the gas and liquid phases were calculated from the integrated extinction coefficient due to the infra-red band at 2350 cm ⁻¹	1. from a cylinder; purified by the usual methods.

AUXILIARY INFORMATION																												
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																											
The solvent was boiled to remove any gases in solution and was then introduced into the absorption vessel without coming into contact with the air. The volume of carbon dioxide absorbed by the liquid from gas buret was then measured. The composition of the solution after equilibrium was attained was measured by chemical analysis. This enabled a check to be made of solubility as calculated from the volume of gas absorbed. The absorption vessel and the gas buret were kept at constant temperature by circulation of water from a thermostat bath.	1. Carbon dioxide - 99.99% pure, from a cylinder supplied by Mathiesen Chemical Company.																											
	2. Cyclohexanol - technical grade from Dow Chemical Company. Impurities were phenol max.0.5 wt%; cyclohexanone max. 0.1wt%; water max. 0.5 wt%

1,2-Ethanediol	298.2	262	0.00382
* Calculated by the compiler assuming a linear function of P _{CO₂} vs x _{CO₂} , i.e. x _{CO₂} (1 atm) = 1/H _{CO₂}			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.		(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent.	
		ESTIMATED ERROR:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility was measured by saturating the solvent solution in a water-jacketed contactor at atmospheric pressure and using a fritted-glass bubbler to disperse the gas. Samples of saturated solution were allowed to drain by gravity into a 50-cm pipet for analysis. The analysis consisted of reacting the sample with an excess of standard sodium hydroxide and back-titrating with standard acid. The composition of solvent was determined from the mass of the components.		1. Matheson Co. Specified as instrument grade of purity 99.5 per cent.	
		2. Fisher Chemical. Certified reagent grade of maximum water content 0.2 per cent.

AUXILIARY INFORMATION										
METHOD/APPARATUS/PROCEDURE: The CO ₂ was contained in a thermostatted metal cylinder connected to a pressure gage, vacuum pump and supply of gas. A tight fitting internal piston sealed with an O-ring fitted into the cylinder so that the volume of gas could be changed by controlled movement of the piston. A measured volume of solvent was injected into the cylinder by a syringe. The absorption of gas was found from the movement of the piston which was necessary to maintain constant pressure. The Henry's law constant, H is defined as			
$H = \lim_{x \rightarrow 0} \left[\frac{f}{x} \right]$			
where f is the fugacity of CO ₂ and x is the mole fraction of CO ₂ in solution.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Solubilities were measured at pressures to 8000 kPa by a method described in ref. (1). The liquid phase was sampled and analysed after the systems had reached equilibrium. Mole fraction solubilities of carbon dioxide fitted the Krichevskii-Il'inskaya equation (3) from which limiting values of Henry's law were found.		1. Obtained from a cylinder; frozen solid evacuated to remove gaseous impurities. 2. Purified by repeated freezing; M.pt 16.0-16.2°C; vapor pressure in the range 50-75°C measured with an isoteniscope and found to be consistent with literature data for a higher temperature (2).

298.15	9.03	0.0277	0.0302
The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket. The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Generated in a Kipp apparatus using marble and hydrochloric acid. (2) 1,2,3-propanetriol. No information.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in solvents, other than alcohols, containing carbon, hydrogen and oxygen.</p> <p>Bodor <i>et al.</i>(1) measured solubility in 2-propanone from 198 K to 318.2 K at partial pressures of carbon dioxide of 7.7 kPa to 97.2 kPa with extrapolation to 101.3 kPa. This data is self consistent and there is no reason to doubt its reliability. Solubility at a partial pressure of 101.3 kPa is given in nine papers (1-9) which together cover the range 198 K to 307.2 K. The general pattern of data is consistent except at 293.2 K and 298.2 K. At 293.2 K values for the mole fraction solubility range from 0.02022 (Felsing(7)) to 0.02317 (Koudelka(4)) and at 298.15 K from 0.01870 (Just(8)) to 0.02108 (Gjaldbaek(9)). The only measurements above 298.2 K are those of Kunerth (5). These need to be confirmed by further work. The following equation for mole fraction solubility at a partial pressure of 101.3 kPa is based upon all the data mentioned above.</p> $\ln x_{\text{CO}_2} = -10.599 + 1980.7/(T/K) - 0.00280 \ln(T/K) \quad (\text{I})$ <p>temperature range = 198-318.2 K standard deviation in x_{CO_2} = 0.0143</p> <p>The following equation is based on data for the temperature range 200.0-298.2 K from (1,6-9).</p> $\ln x_{\text{CO}_2} = -10.313 + 1905.1/(T/K) + 0.0017 \ln(T/K) \quad (\text{II})$ <p>temperature range = 200.1-298.2 K standard deviation in x_{CO_2} = 0.0055</p> <p>Shenderei (10) measured the solubility of carbon dioxide in various solutions of ethyne in 2-propanone at 217.2 K. Extrapolation of the mole fraction solubility for a partial pressure of carbon dioxide to zero concentration of ethyne gives a value of 0.234 for dissolution in pure 2-propanone. The value from equation II is 0.216.</p> <p>Balog-Megyery <i>et al.</i>(2) have published solubilities in sixteen alkanones at 298.15 K and a partial pressure of gas of 101.3 kPa. These range from 2-propanone to 2-undecanone. There is very little change in the mole fraction solubilities calculated from the data. The value for 2-undecanone is 0.0212 and that for 2-propanone is 0.0192. This last value may be compared with the value of 0.0199 from equation II above.</p> <p>Shenderei <i>et al.</i>(11) measured solubility in 2-butanone to high pressures and reported Henry's constants. Estimated mole fraction solubilities at 228.1 K and 248.0 K are 0.1299 and 0.0654 compared with smoothed values of 0.142 and 0.073 for 2-propanone. No other data for 2-butanone at these temperatures are available for comparison.</p> <p>Mole fraction solubilities in cyclopentanone (12), cyclohexanone (13) and in 2,6-dimethylcyclohexanone (14) have been measured at a partial pressure of 101.3 kPa from 273.15 K to 303.15 K by Gallardo <i>et al.</i> Solubility curves lie below that for 2-propanone. There is very little difference in mole fraction solubilities under the same conditions in the three solvents. Mole fraction solubilities are also close to that for 2-methyl-5- (1-methylethenyl)-2-cyclohexen-1-one from Just's data (8) (see Table 1). These measurements on cyclic ketones can be tentatively accepted as reliable.</p> <p>Bodor <i>et al.</i>(1) measured solubilities in acetaldehyde at 33.2 kPa to 101.3 kPa from 198 K to 248.2 K. The data are self-consistent but no other measurements are available for comparison. Mole fraction solubility</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K. July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>values are lower than those for 2-propanone under the same conditions. At 248.2 K and a partial pressure of 1.013 kPa the value for acetaldehyde is 0.047 compared with a value of 0.072 for 2-propanone.</p> <p>Just (8) measured solubility in benzaldehyde at about 101.3 kPa from 288.2 K to 298.2 K. These measurements are in close agreement with measurements by Kunerth (5) from 291.2 K to 309.2 K. An equation for mole fraction solubility at a partial pressure of 101.3 kPa given below is recommended. It is based on the two sets of data.</p> $\ln x_{\text{CO}_2} = -90.097 + 5108.0/(T/K) + 12.023 \ln(T/K)$ <p>temperature range = 288.2-309.2 K standard deviation in x_{CO_2} = 8.9×10^{-5}</p> <p>Solubility in 4-methyl-1,3-dioxolan-2-one (<i>propylene carbonate</i>) has been measured to high pressures by Mantor <i>et al.</i> (15), Zubchenko <i>et al.</i> (16), Shakhova <i>et al.</i> (17), Isaacs <i>et al.</i> (18) and by Murrieta-Guevara <i>et al.</i> (19). These authors have used the data to obtain limiting values of Henry's constant from which the solubility at 101.3 kPa may be estimated. Makranczy <i>et al.</i> (20) have also made measurements to high pressures but values of solubility at 101.3 kPa from these measurements are inconsistent with measurements by other groups. Lenoir <i>et al.</i> (21) have measured limiting values of Henry's constant by a chromatographic method. These values are high compared with other values and may be subject to the limitations of the chromatographic method. Limiting values of Henry's constant from chromatographic measurements by Sweeney (22) are in better agreement with other data. Rivas and Prausnitz (23,24) have reported values of Henry's constant at 263.2 K to 373.2 K calculated from volumes of gas absorbed. The solubility at 293.2 K is also given by Bratzer (25). The evaluator recommends an equation for mole fraction solubility at a partial pressure of gas of 101.3 kPa which is based upon data given in references (15-19,22-25). i.e.</p> $\ln x_{\text{CO}_2} = -36.218 + 2856.7/(T/K) + 3.9003 \ln(T/K)$ <p>temperature range = 228.2-423.2 K standard deviation in x_{CO_2} = 0.00060</p> <p>Meder <i>et al.</i> (26) measured the solubility at partial pressures from 9.3 kPa to 93.0 kPa at 293.2 K. Extrapolation to 101.3 kPa gives a value of x_{CO_2} of about 0.015 compared with a value of 0.0133 from the above equation. These measurements at lower pressures need confirmation by other workers.</p> <p>Vilcu <i>et al.</i> (27) have reported the mole fraction solubility in 1,3-dioxolan-2-one (<i>ethylene carbonate</i>) to be 0.00703 at 101.3 kPa and 313.2 K. This compares with a value of 0.00926 for solubility in propylene carbonate under these conditions.</p> <p>Just (8) measured solubilities in acetic, propanoic and butanoic acids at about 101.3 kPa from 288.2 K to 298.2 K. Kunerth (5) measured solubility in acetic acid at about the same pressure over the range 291.2 K to 309.2 K. These measurements are consistent with those of Just. A smoothing equation for solubility at a partial pressure of 101.3 kPa, based on the two sets of measurements, is given below.</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> $\ln x_{\text{CO}_2} = 76.937 - 2231.8/(T/K) - 12.978 \ln(T/K)$ <p>temperature range = 288.2-309.2 K standard deviation in x_{CO_2} = 0.00012</p> <p>No other measurements are available to confirm Just's data for propanoic and butanoic acids.</p> <p>Ouellet and Dubois (28) measured solubility in 9-octadecanoic acid at 11 kPa to 59 kPa from 296.2 K to 335.2 K. This work is self consistent but no measurements on this or other long chain carboxylic acids are available for comparison. These data for acetic, propanoic, butanoic and 9-octadecanoic acids indicate that mole fraction solubility at a partial pressure of 101.3 kPa increases with carbon number. (Table 1)</p> <p>Just (8) measured solubility in acetic acid anhydride from 288.2 K to 298.2 K. No other data are available.</p> <p>Mole fraction solubilities in alkyl esters of carboxylic acids from the literature are higher than in carboxylic acids or ketones under the same conditions. There is a tendency for values of mole fraction solubilities at 298.2 K and 101.3 kPa to increase with chain length of the parent alkanol and of the parent carboxylic acid. (see Table 1)</p> <p>Just (8) measured solubility in pentyl formate from 288.2 K to 298.2 K. No other data on this system are available for comparison. The mole fraction solubility in methyl acetate at 298.2 K and 101.3 kPa from Just (8) is 0.02260 and from Gjaldbaek and Andersen (9) is 0.00207. The latter measurements are probably the more reliable.</p> <p>Bodor <i>et al.</i> (29) measured solubility in ethyl acetate at partial pressures from 9.6 kPa to 102.4 kPa at 198 K to 318.2 K. The data is self-consistent. Shenderei <i>et al.</i> (11) measured solubility to high pressures at 228.0 K to 248.0 K. Bodor's value of mole fraction solubility at 248.2 K and a partial pressure of 101.3 kPa is 0.0890. The value at 248.0 K and 101.3 kPa from Shenderei is 0.0813. The following smoothing equation for mole fraction solubility at a partial pressure of 101.3 kPa is based upon data from both sources. Differences between the two sets of data must be borne in mind when this equation is used.</p> $\ln x_{\text{CO}_2} = 11.689 + 1063.1/(T/K) - 3.3435 \ln(T/K)$ <p>temperature range = 198-318.2 K standard deviation in x_{CO_2} = 0.0095</p> <p>Solubility in propyl acetate at 298.2 K and a partial pressure of 101.3 kPa was measured by Gjaldbaek and Andersen (9). Solubility in 2-methylpropyl acetate at 293.2 K and 298.2 K was measured by Just (8). There is no reason to doubt the reliability of these measurements but confirmation by other workers is needed.</p> <p>Solubility in pentyl acetate at or close to 101.3 kPa was measured by Just (8) from 288.2 K to 298.2 K and by Kunerth (5) from 291.2 K to 307.2 K. Values of mole fraction solubility at 293.2 K are 0.0266 (Just) and 0.0280 (Kunerth). The following smoothing equation is based on the two sets of data.</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K. July 1991</p>
<p>CRITICAL EVALUATION:</p> $\ln x_{\text{CO}_2} = -79.380 + 4337.8/(T/K) + 10.737 \ln(T/K)$ <p>temperature range = 288.2-307.2 K standard deviation in x_{CO_2} = 0.00056</p> <p>Ouellet and Dubois (28) measured solubility in ethyl stearate at 8 kPa to 78 kPa from 307.2 K to 347.2 K. The data are self-consistent but no other measurements are available for comparison.</p> <p>Arai <i>et al.</i> (30) measured solubility in methyl, ethyl and butyl oleate at 30 kPa to 90 kPa from 273.2 K to 343.2 K. There is very little difference between mole fraction solubilities in the three solvents. The data are self-consistent. No other measurements on these systems are available. Comparison with Ouellet's measurements indicate that mole fraction solubility in oleates is greater than in stearates under the same conditions.</p> <p>There are significant differences between solubilities in 1,2,3-propanetriol triacetate measured by Shakhova <i>et al.</i> (17) from 273.2 K to 328.2 K and those measured by Makranczy <i>et al.</i> (20) from 273.2 K to 303.2 K. Values of mole fraction solubility at a partial pressure of 101.3 kPa at 273.2 K are 0.0466 (Shakhova) and 0.0414 (Makranczy). At 298.2 K the two values are 0.0284 (Shakhova) and 0.0222 (Makranczy). Further measurements on this system are required.</p> <p>The solubility in 1,1'-oxybisethane was measured by Christoff (31) in 1912 at barometric pressure from 273.2 K to 288.2 K. This work indicates that mole fraction solubility, corrected to a partial pressure of 101.3 kPa is close to that in 2-propanone under the same conditions. There is no recent work on the system under these conditions.</p> <p>Bodor (32) measured solubility in tetrahydrofuran at 10.5 kPa to 97.7 kPa from 198 K to 318.2 K. Measurements are self-consistent and there is no reason to doubt their reliability. Mole fraction solubility is high compared with other solvents. No other work on the system is available for comparison.</p> <p>Gallardo <i>et al.</i> (33) reported the mole fraction solubility in 1,4-dioxane at a partial pressure of 101.3 kPa from 285.2 K to 303.2 K. Kassim <i>et al.</i> (34) reported values from 303.2 K to 333.2 K. Values for 303.2 K are 0.01974 (Gallardo) and 0.0192 (Kassim). However Gallardo's measurements show a steep fall in mole fraction solubility with increase in temperature whereas Kassim's measurements show negligible change through the temperature range. The two sets of measurements are therefore not compatible. Further work on this system is required.</p> <p>The limiting value of Henry's constant for dissolution in dipropylene glycol at 298.2-343.2 K was measured by Lenoir <i>et al.</i> (21) by gas-liquid chromatography. No other measurements are available for comparison. Jou <i>et al.</i> (35) measured solubility in triethylene glycol to high pressures at 298.15 K to 398.15 K. Mole fraction solubility at 101.3 kPa can be calculated from the data. Makranczy <i>et al.</i> (36) also investigated this system at 273.15-303.15 K to high pressures. Values of mole fraction solubility at 298.15 K; 101.3 kPa from the two sources are 0.00677 (Makranczy); 0.00846 (Jou). The data from Jou <i>et al.</i> shows greater consistency over the pressure range in which studies were carried out and are likely to be the more reliable. Byeseda <i>et al.</i> (37) measured the solubility in this solvent at 297.1 K and a pressure of 101.6 K. The corresponding value of the mole fraction solubility is 0.0093 compared with a value of 0.0086 by extrapolation of Jou's measurements.</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Makarov <i>et al.</i> (38) measured solubility to high pressures at 293.15 K in two samples of polyethylene glycol having average relative molecular masses of 280 and 400 respectively. In one case the average degree of polymerisation was 6 and in the other case 8.7. Comparison with Jou's data (35) shows that, at a partial pressure of gas of 101.3 K the mole fraction solubility of carbon dioxide increases with the average number of ether linkages in molecules of the solvent. A plot of mole ratio solubility of these compounds with two hydroxyl groups against the number of ether linkages is close to a straight line passing through the mole ratio solubility in ethylene glycol which has no ether linkages (Fig. 1). This indicates that Makarov's data is consistent with Jou's data. The solubility of hydrogen sulfide in polyethylene glycols shows a similar variation with the number of ether linkages (39).</p> <p>Bodor <i>et al.</i> (40) measured solubility in 2-methoxyethanol (ethylene glycol monomethyl ether) at pressures to 99 kPa from 198 K to 318.2 K. Data can be extrapolated to give the solubility at 101.3 kPa. The measurements are self consistent and may be accepted on a tentative basis. Sciamanna and Lynn (41) measured solubility in diethylene glycol monomethyl ether and in triethylene glycol monobutyl ether at 3 to 100 kPa from 288.2 K to 373.2 K. Comparison of these measurements with Bodor's measurements on ethylene glycol monomethyl ether shows again that mole fraction solubility at a pressure of gas of 101.3 kPa increases with the number of ether linkages. When mole ratio solubilities in these compounds with one hydroxyl group are plotted against the number of ether linkages values lie close to a straight line. This line is close to the solubility in ethanol which has no ether linkages (Fig 1).</p> <p>Solubilities in polyethylene glycol diethers have been published by various authors. Makarov (38) measured solubilities in triethyleneglycol diethyl ether, polyethylene glycol diethyl, dipropyl and methylpropyl ethers to high pressures at 293.2 K to 323.2 K. Sciamanna and Lynn (41) measured solubilities in di- and tri- and tetraethylene glycol dimethyl ethers at pressures to 100 kPa from 288.2 K to 373.2 K. Zubchenko and Shakhova (42) also measured the solubility in tetraethylene glycol dimethyl ether at 298.15 K. Sweeney (22) measured the limiting value of Henry's constant at 298.2 K and 323.2 K. Values from both these sources are close to those from Sciamanna's work. Wolfer (43) reported solubility data for polyethylene glycol methyl isopropyl ether. Mole fraction solubilities at 101.3 kPa in all these compounds are greater than in polyglycols having no alkoxy groups but the same number of ether links. Mole ratio solubilities plotted against the number of ether links lie close to a straight line passing through the solubility in diethyl ether which has one ether link (Fig 1).</p> <p>Makranczy <i>et al.</i> (20) measured solubility in methoxytriethylene glycol acetate and butoxytriethylene glycol acetate. Makarov <i>et al.</i> (38) measured solubility in polyethylene glycol diacetate. No other measurements on these solvents are available for comparison. Data for the two monoacetates fall close to values for glycol ethers and diethers having the same number of ether linkages. The data for the diacetate lies closer to corresponding data for polyglycols (Fig. 1)</p> <p>The limiting value of Henry's constant for dissolution in phenol at 323.2 K was measured by Lenoir <i>et al.</i> (21) using the gas-liquid chromatographic method. The mole fraction estimated for a partial pressure of 101.3 kPa is 0.00467 but this value is subject to the limitations associated with the method. Horvath <i>et al.</i> (44) measured solubility in 3-methylphenol at 300.5 K. The value of the mole fraction solubility at a partial pressure of 101.3 kPa is 0.00592. This value is compatible with the value for phenol at 323.2 K estimated from Lenoir's</p>	

Fig. 1 Mole ratio solubilities at 293.15 K and a partial pressure of 101.3 kPa in glycol ethers, glycols, glycol esters, diethyl ether and ethanol as a function of the number of -C-O-C- links in a molecule of the solvent.

△ Glycol diethers and diethyl ether

- a - diethyl ether (31) g - polyethylene glycol methyl isopropyl ether, @Sepasolv (43)
 b - diethylene glycol dimethyl ether (41) h - polyethylene glycol diethyl ether 336 (38)
 c - triethylene glycol dimethyl ether (41) i - polyethylene glycol dipropyl ether (38)
 d - triethylene glycol dimethyl ether (16)¹ j - polyethylene glycol diethyl ether 456 (38)
 e - triethylene glycol diethyl ether (38) k - polyethylene glycol methyl propyl ether (38)
 f - tetraethylene glycol dimethyl ether (41)

■ Glycol monoethers and ethanol

- l - ethanol (smoothed value; see p.128) n - diethylene glycol monomethyl ether (41)
 m - ethylene glycol monomethyl ether (40) o - triethylene glycol butyl ether (41)

▽ Glycols

- p - ethylene glycol² (37) r - polyethylene glycol 280 (38)
 q - triethylene glycol (35) s - polyethylene glycol 400 (38)

× Glycol esters

- t - methoxy triethylene glycol acetate (20) v - polyethylene glycol diacetate (38)
 u - butoxy triethylene glycol acetate (20)

¹ 298.15 K

² 297.1 K

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents, other than Alcohols, Containing Carbon, Oxygen and Hydrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>measurements. Just (8) measured solubility in 2-methoxy-4-(2-propenyl)-phenol at 288.2 K to 298.2 K. Extrapolated values of solubility at a partial pressure of 101.3 kPa are much higher than the apparent solubilities in phenol and 3-methylphenol. This is due to the presence of the methoxy group in this compound. Solubility data for phenols must be accepted on a tentative basis until further measurements on these compounds have been carried out.</p> <p>Kassim <i>et al.</i> (34) measured solubility in dihydro-2-(3H)-furenone at 303.2-333.2 K; 101.3 kPa. Mole fraction solubility is high compared with the reference line based on Raoult's law. These measurements may be accepted on a tentative basis until measurements on this or similar systems are available for comparison.</p> <p>Selected values of mole fraction solubilities in solvents containing oxygen are shown in Table 1 and in Fig 2.</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. Hydrogen

EVALUATOR:

Peter G.T. Fogg,
School of Applied Chemistry,
Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.
July 1991

CRITICAL EVALUATION:

Fig. 2 Mole fraction solubility of carbon dioxide in various solvents containing carbon, oxygen and hydrogen at a partial pressure of gas of 101.3 kPa.

- a - ethyl acetate
- b - 2-propanone
- c - 4-methyl-1,3-dioxolan-2-one (*propylene carbonate*)
- d - pentyl acetate
- e - benzaldehyde
- f - acetic acid

The curves showing the variation of solubility with temperature correspond to equations derived by the evaluator.

A reference line corresponding to values from the Raoult's law equation is also shown.

* calculated by the compiler			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The method is based upon that described by McDaniel (1). The apparatus consisted of a gas buret attached to a levelling tube containing mercury and to the absorption cell containing the solvent under test. The volume of gas absorbed by a measured volume of liquid was measured at a total pressure equal to barometric pressure. The mercury in the gas buret was covered with a layer of solvent so that the gas in the buret was saturated with solvent vapor. Buret and absorption cell were surrounded by heating wire and water jackets fitted with thermometers.		1. produced by heating NaHCO ₃ ; dried with CaCl ₂ ; frozen in liquid air and volatile impurities pumped away; passed over P ₂ O ₅ . 2. commercial sample; purity attested by boiling point and density.	
		ESTIMATED ERROR:	
		δx _{CO₂} = ±5% (compiler)

¹ The authors labeled the solubility as cm ³ (0 °C/760/mmHg) per 1000 g of acetone. The compiler has labeled it 10 ³ x Kuenen coefficient.					
The mole fraction and Ostwald coefficient values were calculated by the compiler.					
The authors fitted the solubility data to the equation					
log m ₁ = -18.085436 + 2615.017/(T/K) + 66.55546 x 10 ⁻³ (T/K)					
- 79.07114 x 10 ⁻⁶ (T/K) ² for the molal solubility of carbon					
dioxide at a partial pressure of 760 mmHg.					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
The apparatus consists of an absorption flask, a manometer, and a gas buret.			(1) Carbon dioxide. Source and purity not stated.		
The absorption flask was in a cryostat with ethyl bromide as the fluid.			(2) 2-Propanone. The best c.p. material available was distilled three times, converted to the NaI addition compound which was distilled and reformed several times. Density, ρ ²⁵ /g cm ⁻³ = 0.78612.		
The gas buret appears to be water jacketed. It appears that the volume of dry carbon dioxide vapor was measured, but the authors do not make a statement to confirm the procedure.			ESTIMATED ERROR:		
The measurement was carried out at a total pressure equal to 760 mmHg CO ₂ + the 2-propanone vapor pressure.			δT/K = ± 0.02		
The authors used an ideal gas molar volume of 22,416.55 cm ³ mol ⁻¹ to convert the gas volumes to moles.			REFERENCES:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid. The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2). The mole fraction values are at one atm pressure assuming Henry's law is obeyed.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:														
Details of the apparatus and procedure are given in refs. (1) and (2). The total pressure was chosen so that the partial pressure of carbon dioxide was about 101.33 kPa. The number of moles of carbon dioxide introduced into the vessel containing the solution was calculated from the volume and pressure of gas introduced, taking non-ideality into account. The number of moles remaining in the gas phase in the reaction vessel was then calculated and the number of moles dissolved in the known weight of solvent found by difference.	1. Supplied by Sociedad Española del Oxígeno; purity 99.998 mol%. 2. Supplied by Fluka; GLC indicated a purity better than 99.5 mol.%; n _D ²⁰ = 1.43657

<p>AUXILIARY INFORMATION</p>									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Solubility apparatus was similar to that used by Ben-Naim and Baer (2) consisting essentially of a gas buret, mercury manometer and solution vessel. The solvent was degassed in the solution vessel. Measurements were carried out on the saturated gas. It appears that the mole fraction at a partial pressure of 1 atmosphere was estimated from the raw experimental data by assuming that Henry's law is obeyed and that the partial pressure of solvent in the gas phase is given by Raoult's law. Some details in ref. (3).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <ol style="list-style-type: none"> 1. Sociedad Española del Oxígeno sample, purity 99.998 mole per cent. 2. AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:												
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.	(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent.												
	ESTIMATED ERROR:												
	δ <i>T</i> /K = ±0.1; δ <i>H</i> /atm = ±6% (estimated by compiler).

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
The equilibrium cell consisted of a Jerguson gauge with a 250 cm ³ gas reservoir. Temperatures were measured by thermocouples and controlled to ±0.5K by an air-bath. Pressures were measured by a Heise Bourdon tube gauge. The cell was charged with solvent. CO ₂ was added to give an appropriate pressure. Nitrogen was added, when necessary, to ensure that total pressure >350 kPa. Gases were circulated by a magnetic pump for at least 8h. The gas phase was analysed by gas chromatography. Samples of the liquid phase were withdrawn, heated at barometric pressure and the quantity of gas evolved found from P-V-T values.			1. no information		
			2. from Eastman Kodak Co.; minimum purity 98%

* calculated by the compiler			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The method is based upon that described by McDaniel (1). The apparatus consisted of a gas buret attached to a levelling tube containing mercury and to the absorption cell containing the solvent under test. The volume of gas absorbed by a measured volume of liquid was measured at a total pressure equal to barometric pressure. The mercury in the gas buret was covered with a layer of solvent so that the gas in the buret was saturated with solvent vapor. Buret and absorption cell were surrounded by heating wire and water jackets fitted with thermometers.		1. produced by heating NaHCO ₃ ; dried with CaCl ₂ ; frozen in liquid air and volatile impurities pumped away; passed over P ₂ O ₅ . 2. commercial sample; purity attested by boiling point and density.	
		ESTIMATED ERROR:

The authors published a graph showing variations of the volume of carbon dioxide absorbed, reduced to 273.15 K and 101.3 kPa, with variations in the partial pressure of carbon dioxide. The partial pressure range was approximately 8-78 kPa. There was linear variation at each of the five temperatures.																			
AUXILIARY INFORMATION																			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																		
The solvent was placed in a glass bulb held in a thermostat bath and connected by flexible copper tubing to a manometer, gas reservoir and vacuum line. Dissolved air was first pumped out of the liquid. The carbon dioxide was then put in contact with the liquid which was agitated for 10-20 min. The quantity of gas absorbed was calculated from the change in pressure and volume of the system. It was also shown that the process of absorption was completely reversible.	1. prepared by heating magnesium carbonate to 350°C; dried by phosphorus pentoxide. 2. density at 40°C = 0.848 g cm ⁻³ ; no further information.

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
A static method was used. The apparatus consisted of an absorption vessel connected to a gas buret and manometers. The system could be evacuated via a vacuum line. Gas was held in a storage bulb. The contents of the absorption vessel could be stirred magnetically and the temperature measured with a thermometer. The apparatus was held at constant temperature by a thermostat.		No information

Solubility measurements at 223-1677 kPa and 273-313 K were given by the authors. These were used by the authors to calculate the limiting value of Henry's constant, H, from the Krichevsky-Il'inskaya equation in the following form:			
$RT \ln \frac{f_2}{x_2} = RT \ln H + \int_{P_1^0}^P \bar{V}_2 dP - A(1-x_1^2)$			
where f ₂ = fugacity of carbon dioxide x ₁ and x ₂ mole fractions of solvent and carbon dioxide respectively. \bar{V}_2 = partial molar volume of carbon dioxide at x ₂ = 0 A = a coefficient			
* calculated by the compiler ** based on measurements at 101.3 kPa only

AUXILIARY INFORMATION																												
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																										
The apparatus is an Ostwald type as described by Just (ref 1), and modified by Skirrow (ref 2). The apparatus consists of a thermostated gas buret and an absorption flask.		(1) Carbon dioxide. No information.																										
The modification involves the use of vapor free gas in the gas buret. A correction is made for the vapor pressure of the solvent. A steel capillary tube with a stopcock, which prevents the gas and the solvent vapor from mixing in the buret, is used to connect the absorption flask and the buret.		(2) Diethyl ether. Merck. Stated to be pure and anhydrous.

298.15	227.2	6.080	6.636
303.15	197.4	5.237	5.812
The compiler calculated the Bunsen and Ostwald coefficients from the author's mole fraction values assuming ideal gas behavior.			
The authors fitted their data to the equation:			
- ln x ₁ = 6.781 ln (T/K) - 34.859 from which they obtained			
ΔH _i ^o /kJ mol ⁻¹ = -2.09, and ΔS _i ^o /J K ⁻¹ mol ⁻¹ = -62 for the transfer			
of one mole of carbon dioxide from the gas phase at 101 kPa to the hypothetical unit mole fraction solution.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus is similar to that of Ben-Naim and Baer (ref 1). It was described in detail in an earlier paper (ref 2).		(1) Carbon dioxide. Sociedad Espanola del Oxigeno. Stated to be 99.998 %.	
The apparatus consists of a gas buret, mercury manometer, and solution vessel. The solvent is degassed in the solution vessel. Measurements were carried out on the solvent vapor saturated gas.		(2) 1,4-Dioxane. Merck and Co. Purity checked by GLC to be ≥ 99 %.	
Literature 1,4-dioxane vapor pressure data were fitted to the equation		ESTIMATED ERROR:

AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:												
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.	(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent.												
	ESTIMATED ERROR:												
	δ <i>T</i> /K = ±0.1; δ <i>H</i> /atm = ±6% (estimated by compiler).

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The solubility of carbon dioxide in triethylene glycol was measured at five temperatures over a partial pressure range of 105 kPa to 20250 kPa using apparatus and procedure described earlier (1). Where necessary nitrogen was added to maintain a total pressure above 200 kPa. The gas phase was analysed by gas chromatography. The liquid phase was analysed by absorption of dissolved gas in sodium hydroxide solution or barium hydroxide solution, addition of excess barium chloride solution and estimation of the barium carbonate which was precipitated. Relationships described by Bender <i>et al.</i> (2) were used to obtain parameters of the Krichevsky-Il'inskaya equation which are given above.		2. from Aldrich Chemicals; water content reduced to less than 0.6 mole percent by heating under vacuum to 120 °C.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Measurements were made over a range of pressures to a maximum of about 4050 kPa. Apparatus for use to about 98 kPa consisted of an absorption vessel fitted with a magnetic stirrer and connected to a surge tank and mercury pressure gage. The absorption vessel was held in a thermostat bath. The vessel was filled with gas under test and the solvent added with a syringe via a diaphragm. The quantity of gas absorbed was calculated from the difference between the final pressure, when the system had reached equilibrium, and the initial pressure. A steel bomb fitted with sampling devices was used for measurements at higher pressures. The bomb containing gas and solvent was rotated in a water bath for 4-5 h before samples of solution were withdrawn. Solubilities were published as Bunsen coefficients. A graph showing the variation of gas solubility with pressure in four of the solvents was also published.

SOURCE AND PURITY OF MATERIALS:

Solvents were from various industrial sources.
Densities and refractive indices at 293.15 K were as follows:

Solvent	Density /g cm ⁻³	Refractive index
polyethylene glycol (RMM 280)	1.12	1.4625
polyethylene glycol (RMM 400)	1.125	1.4625
triethylene glycol diethyl ether	0.9567	1.4266
polyethylene glycol diethyl ether (RMM 336)	1.019	
polyethylene glycol diethyl ether (RMM 456)	1.04	
polyethylene glycol dipropyl ether	1.03	1.4505
polyethylene glycol methylpropyl ether	1.05	1.4539
polyethylene glycol diacetate	1.20	1.4560

3,6,9-Trioxatridecan-1-ol, (triethylene glycol butyl ether); C ₁₀ H ₂₂ O ₄ ; [143-22-6]		3708.0	-10.33 ± 0.6%
[†] Limiting values of Henry's constants, <i>H</i> , were found by use of a modified form of the Krichevsky-Il'inskaya equation i.e. $\ln(f_2/x_2) = \ln H + (A/RT)(x_1^2-1)$ where <i>f</i> ₂ is the fugacity of carbon dioxide <i>x</i> ₂ is the mole fraction of carbon dioxide in the solution <i>x</i> ₁ is the mole fraction of the solvent <i>A</i> is a constant A plot of ln(<i>f</i> ₂ / <i>x</i> ₂) against <i>x</i> ₁ ² -1 has an intercept equal to ln <i>H</i> . Values of the heat of solution, Δ <i>H</i> , fitted the equation $H = H^\circ \exp[(\Delta H_{\text{soln}}/R)(1/T - 1/T^\circ)]$ where <i>T</i> [°] = 298.15 K and <i>H</i> [°] is the value of Henry's constant at 298.15 K.			
AUXILIARY INFORMATION:			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Dried solvent was added to a flask of known weight. The solvent was then heated, degassed, and the flask reweighed. Subsequent steps were automated and data stored in a computer. The solvent vapor pressure was recorded after each increment of temperature of 5 K from 288.2 to 373.2 K. The flask was then cooled, a predetermined mass of gas added and total pressures recorded at intervals of 5 K. The process was repeated with further additions of gas.		Analysis of solvents after being degassed indicated a water content of about 0.1 wt%. 2-(2-Methoxyethoxy)ethanol was referred to by the trade name <i>Dowanol DM</i> ; 3,6,9-Trioxatridecan-1-ol, by the trade name <i>Dowanol TBH</i>

<p>VARIABLES:</p> <p>T/K = 268-393</p>	<p>PREPARED BY:</p> <p>P.G.T. Fogg</p>
<p>EXPERIMENTAL VALUES:</p> <p>The authors stated that BASF had developed <i>Sepasolv MPE</i>, a special mixture of oligoethylene glycol methyl isopropyl ethers with a mean relative molecular mass of 316. Solubilities of several gases were presented on a small scale graph with solubility, α, in units of m³/m³ bar, plotted against temperature. No experimental points were shown. The solubility of CO₂ was plotted over the temperature range -5°C to 120°C. The compiler found that the line plotted for this gas fits the equation:</p> $\log_{10}(\alpha \text{ bar}) = -2.207 + 823.5K/T$ <p>The compiler considers that α/pressure is the volume of gas absorbed, reduced to 273.15 K and 1 bar (or alternatively 1 atm), absorbed by one volume of solvent at the temperature of measurement.</p> <p>The pressure and temperature at which measurements were made was not stated although the graphical information was intended to show behaviour of the solvent from low pressures to pressures greater than 1 bar. Use of the data implies an assumption that the reduced volume of gas absorbed is proportional to partial pressure of gas. The higher the pressure the greater the errors introduced by this assumption.</p> <p>[†]<i>Sepasolv MPE</i> is a registered trademark of BASF.</p>

AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:						
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted. <p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Compounds Containing Halogens 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>The Solubility of carbon dioxide in solvents containing halogens</p> <p>The solubility in tetrachloromethane measured by Gjaldbaek (1) at 298.2 K and about 101.3 kPa is close to a value measured by Horiuti (2) and is consistent with a value measured by Luhning and Schumpe (3) at 293.2 K. Just (4) made measurements from 288.2 K to 298.2 K. The values of the solubility are low compared with values from later work. The mole fraction solubility at 101.3 kPa and 298.2 K from Just's data is 0.00902 compared with 0.01048 (Horiuti) and 0.01070 (Gjaldbaek). A value of 0.00877 obtained by an indirect method by Takahashi <i>et al.</i> (5) can be disregarded. A value of 0.0106, the mean of Gjaldbaek and Horiuti's values, is provisionally recommended for mole fraction solubility at 298.2 K.</p> <p>Kunerth (6) measured the solubility in trichloromethane at about 101.3 kPa from 291.2 K to 309.2 K. A plot of mole fraction solubility against temperature from these data is concave towards the solubility axis. This is not in agreement with the behaviour of other systems under similar conditions and may indicate incorrect allowance for the vapor pressure of solvent at the higher temperatures of measurement. Just (4) reported a solubility value at 298.2 K which is close to Kunerth's value at this temperature. Gjaldbaek (1) reported a solubility at 298.2 K which is high in comparison but is compatible with measurements by Woukoloff (7) at 286 K and of Koudelka (8) at 293.2 K. Values of mole fraction solubility at 298.2 K and 101.3 kPa are 0.0128 (Gjaldbaek); 0.01120 (Just); 0.0113 (Kunerth). Values at 293.2 K are 0.01375 (Koudelka); 0.0121 (Just); 0.01230 (Kunerth). The evaluator considers that the higher and more recent measurements by Gjaldbaek and by Koudelka may be more reliable than the earlier measurements by Just and Kunerth. These data can only be accepted on a provisional basis until the system is re-investigated.</p> <p>Eldridge and co-workers (9,10) measured solubility in dichloromethane over pressure ranges from 310.9 K to 327.6 K. Dantzler <i>et al.</i> (11) measured solubilities in dichlorodifluoromethane and in trichlorofluoromethane over pressure ranges at 273.2 K to 310.9 K. These three sets of data seem to be reliable but measurements by other groups are not available for comparison.</p> <p>The data which are available for 298.2 K and a partial pressure of carbon dioxide of 101.3 kPa show that the mole fraction solubility of gas increases when the hydrogens in dichloromethane or trichloromethane are replaced by fluorine atoms but decreases when they are replaced by chlorine atoms (see Table 1).</p> <p>Solubility in 1,2-dibromoethane was measured at about 101.3 kPa by Gjaldbaek and Andersen (12), Begley <i>et al.</i> (13), Just (4) and Kunerth (6). There is very good agreement between the sets of data. The greatest discrepancy between values of mole fraction solubility is less than 4% i.e. 0.00642 at 309.2 K (Kunerth); 0.00618 at 308.8 K (Begley). The following equation based on data from the four papers is recommended.</p> $\ln x_{\text{CO}_2} = 324.89 - 13552.2/(T/K) - 49.902 \ln(T/K)$ <p>temperature range = 288.2-319.5 K standard deviation in x_{CO_2} = 9.3×10^{-5}</p> <p>Just (4) measured solubility in 1,2-dichloroethane at about 101.3 kPa from 288.2 K to 298.2 K. Luhning and Schumpe (3) measured solubility at 293.2 K and confirmed Just's value at this temperature. Values of mole</p>	

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Compounds Containing Halogens	July 1991

CRITICAL EVALUATION:

fraction solubility at 101.3 kPa fit the following equation.

$$\ln x_{\text{CO}_2} = -9.120 + 1384.9/(T/K)$$

temperature range = 288.2-298.2 K
standard deviation in x_{CO_2} = 3.6×10^{-5}

Just (4) also measured solubilities in 1-bromopentane, 1-chloropentane, 1-chloro-2-methylpropane and 1,2-dibromopropane under the same conditions of temperature and pressure as in 1,2-dichloroethane. Hiraoka and Hildebrand (14) measured solubility in trichlorotrifluoroethane at 101.3 kPa from 276.1 K to 308.5 K. Dantzler *et al.*(11) measured solubility in 1,2-dichloro-1,1,2,2-tetrafluoroethane over pressure ranges from 273.2 K to 310.9 K. Begley *et al.*(13) measured solubility in a mixture of 1-bromo-2-chloropropane and 2-bromo-1-chloropropane. There is no reason to doubt the reliability of any of these measurements but no other data for these systems are available for comparison.

Kobatake and Hildebrand (15) measured the solubility in hexadecafluoroheptane at 101.3 kPa and from 292.2 K to 303.2 K. The measurements are consistent with an earlier measurement of the solubility at 298.25 by Gjaldbaek (1) and may therefore be accepted as reliable. Solubility data for a partial pressure of gas of 101.3 kPa from the two papers fit the following equation

$$\ln x_{\text{CO}_2} = -7.413 + 1056.2/(T/K)$$

temperature range = 292.2-303.2 K
standard deviation in x_{CO_2} = 8.5×10^{-5}

Mole fraction solubilities at a partial pressure of 101.3 kPa for various halogenated alkanes are given in Table 1. and are shown in Fig 1. The available data show that the relative effects of halogen in enhancing the solubility of carbon dioxide are fluorine > chlorine > bromine.

Solubility in L-1822 has been measured by Sargent and Seffl (16) at 101.3 kPa; 298.2 K and 310.2 K and reported as Ostwald coefficients and also as weight fractions. This solvent is reported to be mostly a mixture of 10-carbon linear, branched and cyclic fluorocarbons. The relative molecular mass of a C-10 linear or branched perfluorinated alkane is 538. If this is taken to be the approximate average relative molecular mass of L-1822 then the solubility data correspond to a mole fraction solubility of about 0.0186. The mole fraction solubility in hexadecafluoroheptane at this temperature and pressure is 0.0209. The data reported by Sargent and Seffl are therefore consistent with the nature of the solvent under test.

The solubility in three fluorinated ethers has been studied. FC-80 is mostly a mixture of isomers of heptafluorotetrahydro(nonafluorobutyl)-furan (C₈F₁₆O). Solubility in this solvent at 101.3 kPa has been measured by Tham *et al.*(17) from 298.2 K to 323.2 K. These data are supported by the measurements of Navari *et al.*(18) from 1.3 kPa to 101.3 kPa at 310.2 K. Solubility values at 298.2 K and 310.2 K; 101.3 kPa from Sargent and Seffl (16) are very low in comparison with Tham's values.

Values of x_{CO_2} for FC-80 at 101.3 kPa.

	298.2 K	310.2 K
Tham <i>et al.</i>	0.0223	0.0186
Navari <i>et al.</i>		0.0186
Sargent and Seffl	0.0181	0.0150

COMPONENTS:

1. Carbon dioxide; CO₂;
[124-38-9]
2. Compounds Containing Halogens

EVALUATOR:

Peter G.T. Fogg,
School of Applied Chemistry,
Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.
July 1991

CRITICAL EVALUATION:

Solubility in 1,1,1,2,2,3,3,4,4,5,5,6,6-tridecafluoro-6-[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy]-hexane (C₉F₂₀O) was measured by Tham *et al.* (17) at 298.2 K to 323.2 K; 101.3 kPa. Values are higher than those given by Nychka and Eiback (19). Tham's data are probably the more reliable but confirmation is needed.

x_{CO_2} at 101.3 kPa in C₉F₂₀O

	298.2 K	310.2 K
Tham <i>et al.</i>	0.0250	0.0232
Nychka and Eiback	0.0223	0.0198

Tham *et al.* (17) also measured solubility in 1,1,2,2,3,3,4,4-octafluoro-1,4-bis[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy]-butane (C₁₀F₂₂O₂) at 298.2 K to 323.2 K; 101.3 kPa. There is no reason to doubt the reliability of this work but no other data on the system are available for comparison.

López *et al.* (20) measured solubilities in chlorocyclohexane and bromocyclohexane at 263.2 K to 303.2 K; 101.3 kPa. The work is self-consistent but no other data on these systems are available for comparison. Mole fraction solubilities increase in the order chlorocyclohexane > bromocyclohexane > cyclohexane under these conditions.

Just (4) measured the solubility in 1,3-dichloro-2-propanol from 288.2 K to 298.2 K at 99.5 kPa. The corresponding values of the mole fraction solubility at 101.3 kPa are greater than values for 2-propanol (see Table 1). No other work on the system is available for comparison.

López *et al.* (23) measured solubility in chlorobenzene from 263.2 K to 303.2 K at 101.3 kPa. The measurements are consistent with those of Gjaldbaek and Anderson (12) at 298.2 and about 5% higher than those of Just (4) in the temperature range of 288.2 K to 298.2 K. The following equation for the mole fraction solubility at a partial pressure of 101.3 kPa, based upon the first two sets of data, is recommended.

$$\ln x_{\text{CO}_2} = 4.2360 + 756.71/(T/K) - 2.0001 \ln(T/K)$$

temperature range = 263.2-303.2 K

standard deviation in x_{CO_2} = 3×10^{-5}

López *et al.* (23) also measured solubility in bromobenzene under the same conditions of temperature and pressure. These measurements are consistent with those of Just (4) in the range 288.2 K to 298.2 K. The following equation for mole fraction solubility at a partial pressure of 101.3 kPa, based upon the two sets of data, is recommended.

$$\ln x_{\text{CO}_2} = -5.2127 + 1189.1/(T/K) - 0.63508 \ln(T/K)$$

temperature range = 263.2-303.2 K

standard deviation in x_{CO_2} = 4×10^{-5}

Just also measured solubility in iodobenzene from 288.2 K to 298.2 K at 101.3 kPa. No other measurements on this system are available for comparison. Mole fraction solubilities at 298.2 K and a partial pressure of 101.3 kPa are in the order chlorobenzene > bromobenzene > iodobenzene. Solubility in chlorobenzene is close to that in benzene.

Evans and Battino (21) published the solubility in hexafluorobenzene at 297.7 K and 298.0 K; 101.3 kPa. Mole fraction solubility in this solvent is higher than in chlorobenzene. There is no reason to doubt the reliability of this work which can be accepted on a provisional basis.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Compounds Containing Halogens 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Just (4) measured solubilities in (chloromethyl)-benzene and in (trichloromethyl)-benzene. No other data on these systems are available. The data indicate that substitution of chlorine into the methyl group of methylbenzene lowers the mole fraction solubility at 298.2 K; 101.3 kPa (see Table 1).</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. COMPONENTS:

1. Carbon dioxide; CO₂; [124-38-9]
2. Compounds Containing Halogens

EVALUATOR:

Peter G.T. Fogg,
School of Applied Chemistry,
Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.
July 1991

CRITICAL EVALUATION:

Fig. 1 Mole fraction solubility of carbon dioxide in various solvents containing halogens at a partial pressure of gas of 101.3 kPa.

- a - perfluoro-1-isopropoxyhexane, C₉F₂₀O (17)
- b - hexafluorobenzene (21)
- c - hexadecafluoroheptane (1,15)
- d - 1-chloropentane (4)
- e - trichloromethane (1,8)
- f - 1,2-dichloroethane (3,4)
- g - chlorocyclohexane (20)
- h - tetrachloromethane (1,2,3)
- i - chlorobenzene (12,23)
- j - bromobenzene (4,23)
- k - 1,2-dibromoethane (4,6,12,13)

A reference line corresponding to values from the Raoult's law equation is also shown.

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Tetrachloromethane or carbon tetrachloride; CCl ₄ ; [56-23-5]		ORIGINAL MEASUREMENTS: Just, G. <i>Z. Phys. Chem.</i> <u>1901</u> , 37, 342 - 367.	
VARIABLES: $T/K = 288.15 - 298.15$ $p_1/\text{kPa} = 101.325 \text{ (1 atm)}$		PREPARED BY: M. E. Derrick H. L. Clever	
EXPERIMENTAL VALUES:			
T/K	Mol Fraction $10^3 x_1$	Bunsen Coefficient $\alpha/\text{cm}^3 \text{ (STP) cm}^{-3} \text{ atm}^{-1}$	Ostwald Coefficient $L/\text{cm}^3 \text{ cm}^{-3}$
288.15	10.45	2.47	2.603
293.15	9.94	2.33	2.502
298.15	9.02	2.10	2.294
<p>The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.</p>			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket. The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Generated in a Kipp apparatus using marble and hydrochloric acid. (2) Tetrachloromethane. No information. ESTIMATED ERROR: $\delta L/L = 0.03 \text{ (compiler)}$

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The solvent was degassed by vacuum.		(1) Carbon dioxide. No information.		
The solvent and the gas were brought into contact and a reading of the amount of gas absorbed was made. The readings were repeated after 24 and 48 hours.		(2) Chloroform. Specified as 8919r,075.		
In the author's earlier paper, <i>Comptes rendu</i> 1889, 108, 674, he stated the absorbed gas volume was reduced to the standard temperature and pressure of 0 °C and 760 mmHg. In the present paper the absorbed gas volume is measured at 13 °C and 760 mmHg.		ESTIMATED ERROR:		
		REFERENCES:		
¹ The absorbed gas volume is at a temperature of 286 K and the partial pressure of the carbon dioxide. The Bunsen coefficient values were calculated by the compiler.

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The method is based upon that described by McDaniel (1). The apparatus consisted of a gas buret attached to a levelling tube containing mercury and to the absorption cell containing the solvent under test. The volume of gas absorbed by a measured volume of liquid was measured at a total pressure equal to barometric pressure. The mercury in the gas buret was covered with a layer of solvent so that the gas in the buret was saturated with solvent vapor. Buret and absorption cell were surrounded by heating wire and water jackets fitted with thermometers.		1. produced by heating NaHCO ₃ ; dried with CaCl ₂ ; frozen in liquid air and volatile impurities pumped away; passed over P ₂ O ₅ .	
		2. commercial sample; purity attested by boiling point and density.

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Measurements of solubility were made at pressures from 103 to 2068 kPa using a specially designed cell. Dichloromethane was transferred to the cell and carbon dioxide introduced from a storage cylinder. The cell was rocked in a thermostatted bath until constant pressure was attained. A sample of the liquid phase was then isolated under pressure, withdrawn and weighed. The sample was then allowed to expand and the carbon dioxide estimated by absorption in sodium hydroxide solution and subsequent titration with hydrochloric acid. The partial pressure of dichloromethane in the cell was taken to be proportional to the mole fraction in the liquid. The partial pressure of carbon dioxide was the total pressure minus the partial pressure of dichloromethane. It was found that the mole fraction of carbon dioxide in the liquid was proportional to partial pressure of carbon dioxide to a pressure of about 1000 kPa.		1. Obtained from a cylinder. 2. Technical grade, degassed by distillation.

† extrapolated values estimated by the compiler. In the extrapolation it was assumed that data approximated to the Krichevsky-Il'inskaya equation in the form:							
$\log(P_{\text{CO}_2}/x_{\text{CO}_2}) = \log H - \beta(1-x_s^2)$							
where H is Henry's constant, β is a constant and x _s is the mole fraction of solvent in solution.							
AUXILIARY INFORMATION:							
METHOD/APPARATUS/PROCEDURE:				SOURCE AND PURITY OF MATERIALS:			
The apparatus consisted of a 3 ounce aerosol compatibility tube connected via copper and nylon pressure tubing to a vacuum line, gas cylinder liquid phase sampling valve, gas phase sampling valve and pressure gauge. The aerosol compatibility tube served as the absorption cell and its temperature could be controlled to ±0.1 K by a constant temperature bath. A sample of the fluorocarbon was transferred from the gas cylinder and frozen in the absorption cell by liquid nitrogen. It was purified by repeated melting, refreezing and evacuation. Carbon dioxide was then admitted to the liquid fluorocarbon through a metering valve until the desired pressure was attained. The cell was mechanically shaken until the equilibrium pressure was reached. Samples of the gas phase and of the liquid phase were withdrawn and analysed with a gas chromatograph which had been previously calibrated with synthetic mixture of carbon dioxide and fluorocarbon.				1. Minimum purity 99.15-99.8%			
				2. Fluorocarbons referred to as P11 (trichlorofluoromethane) P12 (dichlorodifluoromethane) P114 (1,2-dichlorotetrafluoroethane) Analysis by gas chromatography indicated a purity of at least 99%

AUXILIARY INFORMATION																									
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																								
The solvent was boiled to remove any gases in solution and was then introduced into the absorption vessel without coming into contact with the air. The volume of carbon dioxide absorbed by the liquid from gas buret was then measured. The composition of the solution after equilibrium was attained was measured by chemical analysis. This enabled a check to be made of solubility as calculated from the volume of gas absorbed. The absorption vessel and the gas buret were kept at constant temperature by circulation of water from a thermostat bath.	1. Carbon dioxide - 99.99% pure, from a cylinder supplied by Mathiesen Chemical Company.																								
	2. 1,2-Dibromoethane - supplied by Dow Chemical Company

308.15	1.589

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a gas measuring buret, an absorption pipet, and a reservoir for the solvent. The buret is thermostated at 25°C, the pipet at any temperature from 5 to 30°C. The pipet contains an iron bar in glass for magnetic stirring. The pure solvent is degassed by freezing with liquid nitrogen, evacuating, then boiling with a heat lamp. The degassing process is repeated three times. The solvent is flowed into the pipet where it is again boiled for final degassing. Manipulation of the apparatus is such that the solvent never comes in contact with stopcock grease. The liquid in the pipet is sealed off by mercury. Its volume is the difference between the capacity of the pipet and the volume of mercury that confines it. Gas is admitted into the pipet. Its exact amount is determined by P-V measurements in the buret before and after introduction of the gas into the pipet. The stirrer is set in motion. Equilibrium is attained within 24 hours.			**SOURCE AND PURITY OF MATERIALS:** (1) Carbon dioxide. Western Gas Inc. Gas passed through a cold trap. (2) 1,1,2-Trichloro-1,2,2-trifluoroethane. Union Carbide Co. Distilled, purity checked by ultraviolet absorbance.

AUXILIARY INFORMATION																									
METHOD APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																								
The solvent was boiled to remove any gases in solution and was then introduced into the absorption vessel without coming into contact with the air. The volume of carbon dioxide absorbed by the liquid from gas buret was then measured. The composition of the solution after equilibrium was attained was measured by chemical analysis. This enabled a check to be made of solubility as calculated from the volume of gas absorbed. The absorption vessel and the gas buret were kept at constant temperature by circulation of water from a thermostat bath. Densities of solvent were also measured by the authors.	1. Carbon dioxide - 99.99% pure, from a cylinder supplied by Mathiesen Chemical Company. 2. 1-Bromo-2-chloropropane and 2-Bromo-1-chloropropane Technical mixture of the two sold as propylene chlorobromide

¹ The mole fraction solubility values adjusted to a gas partial pressure of 101.325 kPa (1 atm) by the compiler assuming Henry's law is obeyed.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: A calibrated all-glass combined manometer and bulb was enclosed in an air thermostat and shaken until equilibrium. Mercury was used for calibration and as confining liquid. The solvent was degassed in the apparatus. The absorbed volume of gas is calculated from the initial and final amounts, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. The mole fraction solubility values are at 1 atm assuming Henry's law is obeyed. Details of the apparatus and procedure are given in ref. 1 and 2.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus and procedure described by Shoor, Walker and Gubbins (1) were used. The solvent was placed in a saturator immersed in a constant temperature bath. The gas was dispersed through the liquid by a fritted glass disk at a rate of about 40 cm ³ m ⁻¹ . After an initial equilibration period of 30 minutes, samples were withdrawn with a Hamilton microliter syringe at 15 minute intervals and analyzed chromatographically (Perkin-Elmer 900 gas chromatograph with thermal conductivity detector). The solubility at one atmosphere partial pressure of the gas was the mean value of three consecutive samples which agreed within the limits of experimental error.		1. Carbon Dioxide. Source not given. Minimum purity 99.6 per cent. 2. FC-80. Minnesota Mining and Manufacturing Co. A mixture of several isomers. The authors also measured the density and viscosity of the solvent at several temperatures. At 298.15 K the density is 1.7657 g cm ⁻³ and the viscosity is 1.3957 centipoise.	
		ESTIMATED ERROR:	
		$\delta T/\text{K} = 0.05$ $\delta x_1/x_1 = 0.005$ (Compiler)

The author's solubility coefficient is probably a Bunsen coefficient.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The solubilities were measured by the gas chromatograph method of Shoor <i>et al.</i> (1). The gas, presaturated with solvent vapor, was passed through the degassed liquid in the saturation cell at a rate of 50 ml m ⁻¹ . Twenty microliter samples of the gas-saturated liquid were withdrawn and analyzed chromatographically at 15 m intervals. When readings remained constant for one hour the solution was assumed to be saturated. The time for saturation was less than 2 hours. The apparatus was calibrated with pure dry oxygen. 	9.71 ¹	2.14	2.34
	9.81 ¹	2.16	2.36
¹ Results obtained by titration, see the paper.			
The mole fraction and Ostwald coefficient values were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.		(1) Carbon dioxide. Prepared from potassium bicarbonate and sulfuric acid. 99.8 - 99.9% CO ₂ .	
The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).		(2) Chlorobenzene. Fractionated by distillation. B.p. (760 mmHg)/°C = 131.95 - 131.98, refractive index n _D (20°C) = 1.3840 - 1.3841.	
The mole fraction values are at one atm pressure assuming Henry's law is obeyed.		ESTIMATED ERROR:	
		δ T/K = ± 0.05 δ x ₁ /x ₁ = ± 0.015

The authors gave the following smoothing equations for the mole fraction solubility of carbon dioxide:			
Chlorobenzene ln x _{CO₂} = -0.2467 + 950.7321/(T/K) - 1.3279 ln(T/K)			
Bromobenzene ln x _{CO₂} = -3.1678 + 1093.8344/(T/K) - 0.9371 ln(T/K)			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The apparatus was similar to that used by Ben Naim and Baer (1) which consisted essentially of a gas buret, mercury manometer and absorption vessel. The apparatus used for these measurements was described in an earlier publication (2).		1. Carbon dioxide supplied by Sociedad Española del Oxígeno, S.A.; purity 99.998% 2. Chlorobenzene - supplied by Merck. Bromobenzene - supplied by Fluka. Purity of each liquid at least 99.5% as indicated by refractive indices and analysis by gas-liquid chromatography.

The Bunsen coefficients were calculated by the compiler.					
The solubility values were adjusted to an oxygen partial pressure of 101.325 kPa (1 atm) by Henry's law.					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3). Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N ₂ trap until the permanent gas residual pressure drops to 5 microns. Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.			SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Either Air Products and Chemicals Inc. or the Matheson Co., Inc. Purest grade available. Minimum purity 99.0 mole per cent (usually > 99.9 mole per cent). (2) Hexafluorobenzene. Imperiel Smelting Co., Avnomouth, U.K. GC purity 99.7%, density, ρ _{298.15} = 1.60596 g cm ⁻³ . Purification described <i>Anal. Chem.</i> <u>1968</u> , <i>40</i> , 224.

		ESTIMATED ERROR: $\delta L/L = 0.03$ (compiler)	
		REFERENCES: 1. Timofejew, W. <i>Z. Phys. Chem.</i> <u>1890</u> , 6, 141. 2. Steiner, P. <i>Ann. Phys. (Leipzig)</i> <u>1894</u> , 52, 275.	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents Containing Nitrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in solvents containing nitrogen</p> <p>Solubility in benzenamine was measured at or near to 101.3 kPa by Just (1) from 288.2 K to 298.2 K, by Kunerth (2) from 293.2 K to 309.2 K, by Gjaldbaek and Andersen (3) at 298.2 K and by Luhning and Schumpe (4) at 293.2 K. There is good correlation between these measurements with a maximum discrepancy of about 3.5%. Values of the mole fraction solubility based on data at 293.2 K are 0.005426 (Luhning) and 0.00524 (Kunerth). Lenoir <i>et al.</i> (5) published a limiting value of Henry's constant from chromatographic measurements at 298.2 K. The mole fraction solubility at a partial pressure of 101.3 kPa estimated from this value is clearly too large (0.0079). The following smoothing equation is based upon data from Just, Kunerth, and from Gjaldbaek and Andersen.</p> $\ln x_{\text{CO}_2} = -193.85 + 9531.6/(T/K) + 27.478 \ln(T/K)$ <p>temperature range = 288.2-309.2 K standard deviation in x_{CO_2} = 4.2×10^{-5}</p> <p>Just (1) measured solubility in 2-methylbenzenamine and in 3-methylbenzenamine at 101.3 kPa and 288.2 K to 298.2 K. The measurements indicate a greater mole fraction solubility in these solvents than in benzenamine under the same conditions. These measurements can be accepted on a provisional basis until they are confirmed by other workers.</p> <p>Just (1), Kunerth (2) and also Gjaldbaek and Andersen (3) measured solubility in pyridine at about 101.3 kPa. There is good correlation between the different measurements. The following smoothing equation for a partial pressure of 101.3 kPa is based upon these measurements.</p> $\ln x_{\text{CO}_2} = 23.871 + 54.519/(T/K) - 5.00061 \ln(T/K)$ <p>temperature range = 291.2-309.2 K standard deviation in x_{CO_2} = 0.00013</p> <p>Henry's constants for solubility in quinoline have been measured by Horvath <i>et al.</i> (6) at 300 K and by Chai and Paulaitis (7) from 298.6 K to 330.2 K. The measurements by Chai and Paulaitis are self consistent and can be provisionally recommended. Values of mole fraction solubility at a partial pressure of 101.3 kPa from these measurements fit the equation below.</p> $\ln x_{\text{CO}_2} = -76.227 + 4508.7/(T/K) + 9.9003 \ln(T/K)$ <p>temperature range = 298.6-330.2 K standard deviation in x_{CO_2} = 6.0×10^{-5}</p> <p>The value of the mole fraction solubility at 300 K from this equation is 0.00884 compared with 0.00939 from Horvath's data.</p> <p>Solubility in perfluorotributylamine was measured by Kobatake and Hildebrand (8) at 101.3 kPa and 277.2 K to 304.3 K. Sargent and Seffl (9) measured solubility at 298.2 K and 310.2 K but the purity of the solvent in this case is uncertain. The values of the mole fraction solubility at a pressure of 101.3 kPa and 298.2 K are 0.0200 (Kobatake) and 0.0218 (Sargent). Data from Kobatake and Hildebrand are likely to be a better measure of the solubility in the pure solvent.</p> <p>Jou <i>et al.</i> (10) measured solubility in <i>N</i>-formyl morpholine at partial pressures of gas of 0.452 kPa to 7090 kPa at 298.2 K to 403.15 K. The data are self-consistent. Kassim <i>et al.</i> (11) measured solubilities at pressures of about 101.3 kPa from 303.2 K to 333.2 K. Mole fraction</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents Containing Nitrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>solubilities at a partial pressure of 101.3 kPa from the two sources do not agree. Values for 313.2 K are 0.0114 (Jou) and 0.0137 (Kassim). Data from Jou <i>et al.</i> extend over a wider temperature and pressure range than those published by Kassim <i>et al.</i> The evaluator considers Jou's data are more likely to be reliable but confirmation is desirable.</p> <p>Solubilities in 3-methyl-1H-pyrazole and N-substituted pyrazoles at 24 kPa to 2533 kPa at 273.2 K to 313.2 K have been reported by Egorova <i>et al.</i> (12) in a deposited document. Substitution on a nitrogen increases mole fraction solubility under these conditions. No other measurements on these systems are available for comparison.</p> <p>Solubility in <i>p</i>-azoxyphenetole was measured by Homfray (13) at 407.2 K to 442.2 K and 118 kPa. There was an apparent decrease in solubility from 418.7 K to 422.2 K followed by a small increase from 429.7 K to 439.7 K. At this temperature there was a marked increase as the solvent changed from a nematic liquid to an isotropic liquid. The solubility then decreased with rise in temperature. Values of the mole fraction solubility at 439.7 K, estimated from the data are 0.00401 (nematic phase) and 0.00549 (isotropic phase). No other work on this system is available for confirmation of these findings.</p> <p>Solubility in 1-methyl-2-pyrrolidinone has been measured by at least fourteen groups (5,11,14-25) over various temperature ranges. Measurements by Demidova <i>et al.</i> (14) and by Murrieta-Guevara <i>et al.</i> (15) extended to 1026 kPa and 1439 kPa respectively. Values of mole fractions solubility for a partial pressure of 101.3 kPa are scattered. Usyukin <i>et al.</i> (16) reported measurements from 253.2 K to 293.2 K. These measurements do not seem to be compatible with data given in the later paper from the same group (14). The evaluator considers that the most reliable measurements are those published in references (11,15,17, 19-23,25) over the temperature range 263.2 K to 393.2 K. Mole fraction solubility at a partial pressure of 101.3 kPa from these sources fit the equation</p> $\ln x_{\text{CO}_2} = -14.820 + 1888.2/(T/K) + 0.7623 \ln(T/K)$ <p>temperature range = 263.15-393.15 K standard deviation in x_{CO_2} = 0.0011</p> <p>The solubility in <i>N,N</i>-dimethylformamide at 27 kPa to 120 kPa from 278 K to 313 K has been published by Haidegger <i>et al.</i> (26). Braude <i>et al.</i> (27) also made measurements over a pressure range at 298.15 K to 353.15 K and reported limiting values of Henry's constant. Rosenthal (28) measured the solubility at 293.2 K and a partial pressure of 101.3 kPa and Byeseda <i>et al.</i> (17) at 297.1 K and 101.6 kPa. A value of the Bunsen coefficient at 298.2 K has been published by du Pont (29). Bunsen coefficients for 213.2 K to 293.2 K have been published by Usyukin and Shleynikov (16). The following equations (I) and (II) are based upon the available data for a partial pressure of 101.3 kPa.</p> $\ln x_{\text{CO}_2} = 47.613 - 159.64/(T/K) - 9.0213 \ln(T/K) \quad (\text{I})$ <p>temperature range = 213.15-353.15 K standard deviation in x_{CO_2} = 0.0026</p> $\ln x_{\text{CO}_2} = -123.79 + 6771.8/(T/K) + 16.994 \ln(T/K) \quad (\text{II})$ <p>temperature range = 273.15-353.15 K standard deviation in x_{CO_2} = 0.0014</p> <p>Shenderei (30) measured the solubility of carbon dioxide in solutions of ethyne in <i>N,N</i>-dimethylformamide at 218.15 K and pressures of carbon</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Solvents Containing Nitrogen 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>dioxide from 13.3 kPa to 101.3 kPa. Extrapolation of the data to zero concentration of ethyne gives a mole fraction solubility of carbon dioxide of 0.169 at a partial pressure of 101.3 kPa. The corresponding value from equation (I) above is 0.1827 ± 0.0026.</p> <p>Solubility in nitrobenzene has been measured at pressures close to 101.3 kPa by Gjaldbaek and Andersen (3) at 298.2 K, by Luhning and Schumpe (4) at 293.2 K and by Just (1) from 288.2 K to 298.2 K. Lenoir <i>et al.</i> (5) published a limiting value from chromatographic measurements at 298.2 K. The value of the mole fraction solubility at 298.2 K and a partial pressure of 101.3 kPa from Gjaldbaek's data is 0.01015 and from Just's data is 0.0103. The value from Lenoir's data is 0.0130 and is subject to uncertainty because of the possibility of surface adsorption during the chromatographic process. Values at 293.2 K are 0.0112 (Just) and 0.0114 (Luhning). A smoothing equation based upon work by Gjaldbaek and Andersen, Just and by Luhning and Schumpe can be recommended for the limited temperature range covered.</p> $\ln x_{\text{CO}_2} = -9.583 + 1492.6/(T/K)$ <p>temperature range = 288.2-298.2 K standard deviation in x_{CO_2} = 0.00016</p> <p>Solubility in hydrogen cyanide (31) and various nitriles (3,32,33) have been measured. A selection of values of solubilities at a partial pressure of 101.3 kPa are shown in Table 1. No estimation of the reliability of these measurements can be given.</p> <p>Wehner <i>et al.</i> (34) reported the solubility of carbon dioxide in <i>N</i>-methyl-ε-caprolactam at 293.2 K. Mole fraction solubility at a partial pressure of 101.3 kPa calculated from the data is close to that for dissolution in propanenitrile at 298.2 K reported by Gjaldbaek and Andersen (3) but no estimation of the reliability of the measurement can be made.</p> <p>The solubility in formamide at 298 K has been given by Takahashi <i>et al.</i> (35). The indirect method which was used is of uncertain reliability.</p> <p>Selected values of mole fraction solubilities at a partial pressure of 101.3 kPa in compounds containing nitrogen are shown in Table 1 and Fig 1.</p> <p>REFERENCES</p> <ol style="list-style-type: none"> 1. School of Applied Chemistry,
Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.

July 1991

CRITICAL EVALUATION:

Fig. 1 Mole fraction solubility of carbon dioxide in various solvents containing nitrogen at a partial pressure of gas of 101.3 kPa.

- a - 1-methyl-2-pyrrolidinone
- b - *N,N*-dimethylformamide
- c - pyridine
- d - nitrobenzene
- e - quinoline
- f - benzenamine
- g - perfluorotributylamine (8)

The curves showing the variation of solubility with temperature correspond to equations derived by the evaluator.

A reference line corresponding to values from the Raoult's law equation is also shown.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The method is based upon that described by McDaniel (1). The apparatus consisted of a gas buret attached to a levelling tube containing mercury and to the absorption cell containing the solvent under test. The volume of gas absorbed by a measured volume of liquid was measured at a total pressure equal to barometric pressure. The mercury in the gas buret was covered with a layer of solvent so that the gas in the buret was saturated with solvent vapor. Buret and absorption cell were surrounded by heating wire and water jackets fitted with thermometers.		1. produced by heating NaHCO ₃ ; dried with CaCl ₂ ; frozen in liquid air and volatile impurities pumped away; passed over P ₂ O ₅ .	
		2. commercial sample; purity attested by boiling point and density.

The mole fraction and Ostwald coefficient values were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid. The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2). The mole fraction values are at one atm pressure assuming Henry's law is obeyed.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Prepared from potassium bicarbonate and sulfuric acid. 99.8 - 99.9% CO ₂ . (2) Benzenamine. Merck and Co. Puriss. Fractional distillation in vacuum. B.p. (760 mmHg)/°C = 184.32 - 184.34, refractive index $n_D(20^\circ\text{C}) = 1.5864$. ESTIMATED ERROR: $\delta T/K = \pm 0.05$ $\delta x_1/x_1 = \pm 0.015$ REFERENCES: 1. Lannung, A. <i>J. Am. Chem. AUXILIARY INFORMATION									
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:								
A conventional gas-liquid chromatographic unit was used with helium as carrier gas. Values of Henry's constant were calculated from retention times extrapolated to zero sample size. Values correspond to very low partial pressure of carbon dioxide. Surface adsorption can cause appreciable errors in this method of measuring Henry's law constants.	1. Sample from L'Air Liquide; minimum purity 99.9 mol%								
	2. Sample from Touzart and Matignon or from Serlabo of purity 99 mol%

AUXILIARY INFORMATION												
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid. The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2). The mole fraction values are at one atm pressure assuming Henry's law is obeyed.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
The apparatus consists of a gas measuring buret, an absorption pipet, and a reservoir for the solvent. The buret is thermostated at 25°C, the pipet at any temperature from 5 to 30 °C. The pipet contains an iron bar in glass for magnetic stirring. The pure solvent is degassed by freezing with liquid nitrogen, evacuating, then boiling with a heat lamp. The degassing process is repeated three times. The solvent is flowed into the pipet where it is again boiled for final degassing. Manipulation of the apparatus is such that the solvent never comes in contact with stopcock grease. The liquid in the pipet is sealed off by mercury. Its volume is the difference between the capacity of the pipet and the volume of mercury that confines it. Gas is admitted into the pipet. Its exact amount is determined by P-V measurements in the buret before and after introduction of the gas into the pipet. The stirrer is set in motion. Equilibrium is attained within 24 hours.			(1) Carbon dioxide. California Dry Ice Co. Standard grade. Dried by passing through a trap at dry ice-acetone temperature, and tubes containing CaCl ₂ then P ₂ O ₅ . The dried gas was distilled at liquid N ₂ temperature several times.		
			(2) Perfluorotriethylamine. Minnesota Mining and Manufacturing Co. Dried, fractionated, boiling point 178.5 - 179.0°C. Density, ρ/g cm ⁻³ = 1.872.

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:																	
The equilibrium apparatus is a 50 cm ³ three neck flask equipped with a water condenser, a thermometer, and a gas dispersing tube extending below the fluid surface level. Between 25 and 35 cm ³ of solvent are placed in the flask. Gas is bubbled through the solvent for 2 - 3 h. An 80 microliter sample is slowly taken into a gas tight syringe. The sample is injected into a gas chromatograph. The results of three sampling and analyses are averaged.		(1) Carbon dioxide. Source not given. Commercial cylinder, or dry ice.																	
The chromatograph is an F and M Model 720 equipped with a thermal conductivity detector at 320 °C, and a 6' by ¼" stainless steel column packed with 50/80 mesh Parapak-P at room temperature. The apparatus is calibrated with pure gas samples.		(2) FC-47. Minnesota Mining and Manufacturing Co. * calculated by the compiler from the parameters for the Krichevsky-Il'inskaya equation given above.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The solubility of carbon dioxide in N-formyl morpholine was measured at five temperatures over a partial pressure range from 0.8 kPa to about 7000 kPa using apparatus and procedure described earlier (1). Where necessary nitrogen was added to maintain a total pressure above 200 kPa. The gas phase was analysed by gas chromatography. The liquid phase was analysed by absorption of dissolved gas in sodium hydroxide solution and subsequent estimation of carbonate by precipitation as barium carbonate. The data were correlated by the Peng-Robinson equation of state as described earlier (2). Relationships described by Bender et al.(3) were used to obtain parameters of the Krichevsky-Il'inskaya equation (4) which are given above.		No information

* Solubility of carbon dioxide was given as the volume of gas, reduced to 273.15 K and 101.325 kPa absorbed by unit volume of the solvent.					
** Henry's law constant, <i>H</i> , was defined by the authors as					
$\frac{\text{mole fraction solubility at a pressure of 760 mmHg}}{760 \text{ mmHg}}$					
† calculated by the compiler. The density was taken to be equal to 0.936, the value for 1-ethyl-3-methyl-1 <i>H</i> -pyrazole at 293.15 K (1).					
¶ extrapolated value					
Solubilities in the range 10 to 25 atm (1013-2533 kPa) at 273.15 and 313.15 K were given in graphical form.

The calculated manometer reading is the value expected if there is no gas absorption.							
The difference between the calculated and the observed manometer reading is a measure of the gas absorbed. The manometer tube had a volume of 0.03 cm ³ per cm of length.							
AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:				SOURCE AND PURITY OF MATERIALS:			
A 2 g sample is enclosed in a bulb and manometer system of known volume. The bulb and contents are in a refluxing aniline bath. The temperature is controlled by the pressure over the aniline.				(1) Carbon dioxide. Dry gas.			
At each temperature the gas volume is compared with a gas volume calculated assuming ideal gas behavior and no gas absorption by the solvent. The difference in the volumes is the gas volume absorbed by the sample at a temperature of 293 K and a pressure of 118 kPa (88.5 cmHg).				(2) <i>p</i> -Azoxyphenetole. Commercial sample of unknown purity. Prepared from purified <i>p</i> -nitrophenetole by heating with sodium in absolute alcohol. Product recrystallised 20 times from alcohol. Solid to nematic liquid transition 138.5 °C, nematic to isotropic liquid transition 168 °C.			
The solvent volume is stated to be 1.824 cm ³ at 145.5 °C and 1.866 cm ³ at 166.5 °C. The compiler calculated the CO ₂ absorption in the sample and in 100 cm ³ of solvent assuming the sample volumes above.				ESTIMATED ERROR: 5 ~ 10 per cent (Compiler)

Henry's constant, H, is defined by the equation:																																			
$H = \frac{P_{\text{CO}_2}}{x_{\text{CO}_2}}$																																			
The authors published a graph which showed that the variation of mole fraction solubility with partial pressure of carbon dioxide was linear in the experimental pressure range (13-101 kPa).																																			
* calculated by the compiler.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.		(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 per cent cent.	
		ESTIMATED ERROR:	
		δT/K = ±0.1; δH/atm = ±6% (estimated by compiler).

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:										
The CO ₂ was contained in a thermostatted metal cylinder connected to a pressure gage, vacuum pump and supply of gas. A tight fitting internal piston sealed with an O-ring fitted into the cylinder so that the volume of gas could be changed by controlled movement of the piston. A measured volume of solvent was injected into the cylinder by a syringe. The absorption of gas was found from the movement of the piston which was necessary to maintain constant pressure.	2. Sample referred to as [®] MPYROL.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The CO ₂ was contained in a thermostatted metal cylinder connected to a pressure gage, vacuum pump and supply of gas. A tight fitting internal piston sealed with an O-ring fitted into the cylinder so that the volume of gas could be changed by controlled movement of the piston. A measured volume of solvent was injected into the cylinder by a syringe. The absorption of gas was found from the movement of the piston which was necessary to maintain constant pressure. AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:						
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.	(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent.

AUXILIARY INFORMATION											
METHOD/APPARATUS/PROCEDURE: Solubilities were measured by a static method. Liquid hydrocyanic acid was introduced into a calibrated buret. A second calibrated buret contained carbon dioxide over mercury. Burets were maintained at the required temperature by circulation of a coolant through outer jackets. The reduction in volume of carbon dioxide at a total pressure equal to barometric pressure was measured when taps connecting the burets were opened. The volumes of gas were corrected to 273.15 K.	SOURCE AND PURITY OF MATERIALS: 1. Commercial sample dried with <i>Actigel</i> before use. 2. Refluxed for 2.5 h to remove dissolved gases and then sealed in ampoules.

The mole fraction and Ostwald coefficient values were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid. The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2). The mole fraction values are at one atm pressure assuming Henry's law is obeyed.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Compounds of Phosphorus, Silicon or Sulfur	July 1991

CRITICAL EVALUATION:

Solubility of carbon dioxide in solvents containing phosphorus, silicon or sulfur.

Solubility in solvents containing phosphorus

Mole fraction solubility in hexamethylphosphoric triamide at a partial pressure of 101.3 kPa may be estimated from data published by Bryukhanova and Nikitina (1), Schay *et al.*(2), Lenoir *et al.*(3) and Bratzler *et al.*(4). There is poor agreement between the sets of data. A selection of values of mole fraction solubility at 101.3 kPa are given below.

	293.2 K	298.2 K	333.2 K
Bryukhanova and Nikitina	0.0338*	0.0313*	0.01942
Schay <i>et al.</i>	0.0303	0.0282	0.0144
Lenoir <i>et al.</i>		0.0329	
Bratzler <i>et al.</i>	0.037		

* extrapolated

The following equation based upon data from the four sources can be used as an approximate guide to solubility at 101.3 kPa in this solvent. Further measurements are needed to resolve discrepancies between the solubility data.

$$\ln x_{\text{CO}_2} = -9.074 + 1667.6/(T/K)$$

temperature range = 273.2-363.2 K
standard deviation in values of x_{CO_2} = 0.0030

Solubility in tributyl phosphate at 223.2 K to 313.2 K from 13.6 kPa to 101.0 kPa has been published by Kosyakov *et al.*(5). Henry's constant at various temperatures from 243.2 K to 383.2 K have been published by Lenoir *et al.*(3), Gudashova and Furmer (6), Sweeney (7), and Vei *et al.*(8). There is satisfactory agreement between mole fraction solubilities at a partial pressure of 101.3 kPa calculated from data from the five sources. The recommended smoothing equation is given below.

$$\ln x_{\text{CO}_2} = 17.505 + 591.57/(T/K) - 4.0173 \ln(T/K)$$

temperature range = 223.2-383.2 K
standard deviation in values of x_{CO_2} = 0.0055

Solubility in triethyl phosphate was measured at 298.15 K; 101.3 kPa by Schay *et al.*(2). Lenoir *et al.*(3) reported a limiting value of Henry's constant at 325.7 K measured by gas-liquid chromatography. The corresponding values of mole fraction solubility at a partial pressure of 101.3 kPa are compatible with each other.

Lenoir *et al.*(3) also reported values of Henry's constant for the trimethyl, tripropyl and tris(2-methylpropyl) esters of phosphoric acid. No other measurements on these systems are available for comparison.

Solubility in solvents containing silicon

Wilcock *et al.*(9) measured solubility in octamethylcyclotetrasiloxane at 292.2 K to 313.1 K; 101.3 kPa. The data are likely to be reliable but no other measurements on this system are available for comparison. Mole fraction solubility is high compared with a reference line based upon Raoult's law.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Compounds of Phosphorus, Silicon or Sulfur 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility in tetramethyl silane at 291.5 K has been reported by Horsman-van den Dool and Warman (10). The solubility measurement needs to be confirmed by other workers before it can be recommended.</p> <p>Solubility in solvents containing sulfur</p> <p>-----</p> <p>Kassim <i>et al.</i> (11) measured solubility in tetrahydrothiophene, 1,1-dioxide at 303.2 K to 333.2 K; 101.3 kPa. Xu <i>et al.</i> (12) reported solubility measured at about 100 kPa from 303.2 K to 359.9 K. Roberts and Mather (13) measured solubility to high pressures at 313.2 K and 373.2 K. Rivas and Prausnitz (14) published Henry's constants for 303.2 K to 373.2 K. Murrieta-Guevara <i>et al.</i> (15) reported limiting values of Henry's constants from 303.2 K to 373.2 K.</p> <p>The evaluator recommends the following equation based upon data from references (11-14) for the mole fraction solubility at a partial pressure of 101.3 kPa.</p> $\ln x_{\text{CO}_2} = -67.177 + 4443.1/(T/K) + 8.4001 \ln(T/K)$ <p>temperature range = 303.2-373.2 K standard deviation in $x_{\text{CO}_2} = 1.9 \times 10^{-4}$</p> <p>Values estimated from Henry's constants published by Murrieta-Guevara <i>et al.</i> (15) differ from values from this equation by 8%, 2% and 12% at 303.2 K, 323.2 K and 373.2 K respectively.</p> <p>Solubility in carbon disulfide at or close to 101.3 kPa has been reported by Just (16) from 288.2 K to 298.2 K and Kobatake and Hildebrand (17) from 281.7 K to 306.4 K. Solubility at lower pressures has been reported by Woukoloff (18) from 280.2 K to 293.7 K and Gjaldbaek (19) from 298.1 to 298.5 K. There is good agreement between values of mole fraction solubility corrected to a partial pressure of 101.3 kPa from data given by Kobatake and Hildebrand, Woukoloff, and by Gjaldbaek. A smoothing equation for these values are given below. Data published by Just are very low when compared with that from the other sources.</p> $\ln x_{\text{CO}_2} = 65.328 - 2496.8/(T/K) - 11.0008 \ln(T/K)$ <p>temperature range = 280.2-306.4 K standard deviation in $x_{\text{CO}_2} = 3.8 \times 10^{-5}$</p> <p>The value mole fraction solubility in sulfinylbismethane at 101.3 kPa and 298.2 K published by Dymond (20) is 0.00908. Lenoir <i>et al.</i> (3) reported a limiting value of Henry's law constant measured by gas-liquid chromatography at this temperature. This corresponds to a mole fraction solubility at 101.3 kPa of about 0.00943. Solubilities measured by gas chromatography are always subject to uncertainty because of the possibility of surface effects affecting the result. Dymond's value may therefore be the more reliable one but confirmation by other measurements is needed.</p> <p>Selected values of solubilities in solvents containing phosphorus or silicon are given in Table 1 and shown in Fig 1.</p>

AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:						
A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted.	(1) L'Air Liquide sample, minimum purity 99.9 mole per cent. (2) Touzart and Matignon or Serlabo sample, purity 99 mole per cent.						
	ESTIMATED ERROR:						
	$\delta T/K = \pm 0.1$; $\delta H/atm = \pm 6\%$ (estimated by compiler).

EXPERIMENTAL VALUES:				
Solubilities were measured at various pressures to a maximum of 40 atm (4053 kPa) and interpreted by the Krichevskii-Il'inskaya equation in the form				
$\log(P_2/x_2) = \log H - \beta(1-x_1^2)$				
<i>P</i> ₂ is the partial pressure of carbon dioxide, <i>x</i> ₂ the mole fraction of carbon dioxide in the liquid phase, <i>H</i> the limiting value of the Henry's law constant, <i>β</i> a constant and <i>x</i> ₁ the mole fraction of hexametapol in the liquid phase. Henry's law constant is taken to be the ratio of the partial pressure of carbon dioxide to the mole fraction of carbon dioxide in the liquid phase.

AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE: A cylindrical glass container of approximately 15 cm^3 volume is partly filled with solvent and closed with a half-hole septum. An amount of the gaseous solute is added to the container. The closed container is shaken for 30 minutes. Samples of both the vapor and liquid phases are taken in a calibrated syringes. The samples are injected into a gas chromatograph. The Ostwald coefficient is calculated from the known sample size and the measured peak areas. The chromatograph is a Hewlett-Packard model 5750 equipped with a thermal conductivity cell detector. The carrier gas is helium. A 200 cm Porapak Q column is used for the separation.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Baker Chemical Co. Instrument grade, 99.99 per cent. Used as received. (2) Tetramethyl silane. Merck. Uvasol grade. Impurities which give the same retention time as the gas are removed before the experiment by adsorption or distillation. ESTIMATED ERROR: $\delta L/L = \pm 0.05$ REFERENCES:

METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
The apparatus was similar to that described by Jou et al.(1). The sulfolane was introduced into a windowed equilibrium cell in a constant temperature bath. Gas was added until sufficient pressure was reached. The gas was circulated by a magnetic pump and bubbled through the liquid until the pressure remained constant for several hours. The vapor phase was then analysed by gas chromatography. Samples of the liquid phase were withdrawn, added to a solution of sodium hydroxide and the amount of carbon dioxide in the samples found by titration.	2. The apparatus was similar to that described by Haimour and Sandall (1) which consisted essentially of a glass flask maintained at constant temperature connected to a gas buret. The flask was first purged with gas under test. A measured volume of solvent was then injected into the flask. The flask was mechanically shaken and the reduction of volume of gas in the gas buret recorded.	1. Carbon dioxide supplied by Union Carbide Canada Ltd.; purity at least 99.9% 2. ¹ The mole fraction solubility values were adjusted to a gas partial pressure of 101.325 kPa by the compiler assuming that Henry's law is obeyed.

AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: A calibrated all-glass combined manometer and bulb was enclosed in an air thermostat and shaken until equilibrium. Mercury was used for calibration and as confining liquid. The solvent was degassed in the apparatus. The absorbed volume of gas is calculated from the initial and final amounts, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. The mole fraction solubility values are at 1 atm assuming Henry's law is obeyed. Details of the apparatus and procedure are given in ref. 1 and 2.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a gas measuring buret, an absorption pipet, and a reservoir for the solvent. The buret is thermostated at 25°C, the pipet at any temperature from 5 to 30°C. The pipet contains an iron bar in glass for magnetic stirring. The pure solvent is degassed by freezing with liquid nitrogen, evacuating, then boiling with a heat lamp. The degassing process is repeated three times. The solvent is flowed into the pipet where it is again boiled for final degassing. Manipulation of the apparatus is such that the solvent never comes in contact with stopcock grease. The liquid in the pipet is sealed off by mercury. Its volume is the difference between the capacity of the pipet and the volume of mercury that confines it. Gas is admitted into the pipet. Its exact amount is determined by P-V measurements in the buret before and after introduction of the gas into the pipet. The stirrer is set in motion. Equilibrium is attained within 24 hours.			SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. California Dry Ice Co. Standard grade. Dried by passing through a trap at dry ice-acetone temperature, and tubes containing CaCl ₂ then P ₂ O ₅ . The dried gas was distilled at liquid N ₂ temperature several times. (2) Carbon disulfide. Mallinckrodt Chemical Works. Analytical Reagent grade. Shaken successively with Hg and HgCl ₂ , filtered, distilled, and stored over Hg more than 5 days before use.		
			ESTIMATED ERROR: $\delta T/K = 0.02$ $\delta x_1/x_1 = 0.003$

AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE: A conventional gas-liquid chromatographic unit fitted with a thermal conductivity detector was used. The carrier gas was helium. The value of Henry's law constant was calculated from the retention time. The value applies to very low partial pressures of gas and there may be a substantial difference from that measured at 1 atm. pressure. There is also considerable uncertainty in the value of Henry's constant since surface adsorption was not allowed for although its possible existence was noted. <p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Mixed Solvents 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in mixed solvents</p> <p>Sichkova and co-workers (1,2) have measured the solubility of carbon dioxide in solutions of 2-aminoethanol in various organic solvents. Measurements on solutions in methanol were made at partial pressures of carbon dioxide from 6.7 kPa to 101.3 kPa, temperatures from 223.2 K to 293.2 K and concentrations of 2-aminoethanol of 5, 15 and 18 wt%. At a fixed temperature and a fixed concentration of 2-aminoethanol there is relatively little change in the mole fraction solubility of carbon dioxide with change in pressure over the pressure range studied. At 293.2 K and 15 wt% of 2-aminoethanol the mole fraction solubility at 6.7 kPa is 0.0391 and at 101.3 kPa is 0.0629. This behaviour is similar to that of aqueous solution of aminoalkanol. At a fixed partial pressure of carbon dioxide and a fixed temperature, extrapolation of mole fraction solubility of carbon dioxide to zero concentration of 2-aminoethanol gives a solubility close to that predicted from the smoothing equation recommended for solubility in methanol (see page 128). Solutions of 2-aminoethanol in other solvents were studied at one concentration of 2-aminoethanol (2.5 mol dm⁻³) and, in most cases, at one temperature, 293.2 K, only. The nature of the solvent affects the absorption of carbon dioxide to some extent. At 293 K, 99.1 kPa the solubility in benzenemethanol solution is 30.7 cm³ gas (corrected to 101.3 kPa and 273.2 K)/cm³ of solvent. The corresponding solubility in <i>N,N</i>-dimethylformamide solution at 98 kPa is 40.6 cm³/cm³. There is no reason to doubt the reliability of the measurements on 2-aminoethanol solutions reported by Sichkova and co-workers. The data may be accepted on a provisional basis.</p> <p>Rivas and Prausnitz (3) measured solubility in solutions of 2-aminoethanol in 1-methyl-2-pyrrolidinone. This system was also studied by Sichkova <i>et al.</i> Data are presented in the form of small scale graphs. The graph for solutions containing 3 and 5 wt% of 2-aminoethanol shows the variation of mole fraction of carbon dioxide with partial pressure of carbon dioxide for each solution. A second graph for a solution of 15 wt% of aminoethanol shows the variation of moles of CO₂/dm³ with partial pressure of carbon dioxide. The first graph indicates that absorption of carbon dioxide per unit volume of solvent increases with concentration of 2-aminoethanol whereas the second graph indicates that the absorption in the 15 wt% solution is less than in the 5% solution for the same partial pressure of carbon dioxide. In the opinion of the evaluator the second graph should also be labelled to show the variation of mole fraction solubility of carbon dioxide with partial pressure of gas. The variation is then in accord with the variation in solubility in a solution of approximately 13 wt% reported by Sichkova <i>et al.</i></p> <p>Rivas and Prausnitz (4) also measured the solubility of carbon dioxide in a solution of 2-(2-aminoethoxy)-ethanol at 263.1 K and 298.3 K and pressures from 7.9 kPa to 35.0 kPa. These data are consistent with data for solutions of 2-aminoethanol.</p> <p>Takahashi <i>et al.</i> (5) measured solubility of carbon dioxide in benzene, tetrachloromethane, 1-propanol, 1-octanol, 2-methyl-1-propanol and formamide and mixtures of pairs of these solvents. They used an indirect method in which the rate of absorption of gas was measured. The solubility data for the pure solvents are low compared with values found by other workers using conventional methods. The mole fraction solubility in ethanol at 298.2 K; 101.3 kPa from this work is 0.00624 compared with a smoothed value from other sources of 0.00727. The value for benzene is 0.00824 compared with a smoothed value of 0.00927. Viscosity of mixtures was also measured. The authors found a correlation between the variation of their solubility values and variation of viscosity as composition of a mixture was varied.</p>	

COMPONENTS:

1. Carbon dioxide; CO₂;
[124-38-9]
2. Mixed Solvents

EVALUATOR:

Peter G.T. Fogg,
School of Applied Chemistry;
Polytechnic of North London,
Holloway Road, London, N7 8DB, U.K.

July 1991

CRITICAL EVALUATION:

Koudelka (6) measured solubilities in pure samples of methanol, 2-propanone, trichloromethane, and benzene and in mixtures of pairs of these solvents. Measurements were carried out at 293.15 K and data given for a partial pressure of gas of 101.3 kPa. Solubility data on the pure solvents are in good accord with data obtained by other workers. It is therefore likely that data for the mixtures are reliable. In all cases the variation of mole fraction solubility of carbon dioxide with molar composition of the mixed solvent lay on smooth curves. In one case, that of mixtures of methanol and trichloromethane, the mole fraction solubility of carbon dioxide passes through a minimum.

Byrne *et al.* (7) measured Ostwald coefficients for dissolution of carbon dioxide in solutions of cephalin, lecithin or cholesterol in benzene. In each case the Ostwald coefficient was lower than the value for pure benzene. Similar measurements were made of the solubility of cholesterol in 2-methyl-1-propanol but, in this case, the added solid did not affect the value of the Bunsen coefficient. There is no reason to doubt the reliability of this work but no other measurements on these systems are available for comparison.

Rosenthal (8) measured the effects on the solubility of carbon dioxide of adding polymeric material to various solvents. Cellulose acetate lowered the Ostwald coefficient for dissolution in *N,N*-dimethylformamide and for dissolution in 2-propanone. Polystyrene and polyisobutylene both lowered the coefficient for dissolution in benzene. Polyacrylonitrile raised the coefficient for dissolution in *N,N*-dimethylformamide. In all cases the effects were small. The addition of 0.0987 g of polystyrene of relative molecular mass 180 000 lowered the Ostwald coefficient for dissolution in benzene from 2.66 to 2.44 at 293.15 K. No similar measurements are available to confirm these results. However the measurements of solubility in the pure liquids, in the absence of polymeric material, which was carried out as part of the same research, are in good agreement with measurements by other workers.

Rosenthal (8) measured the solubility of carbon dioxide in solutions of sodium iodide in 2-propanone. The molal concentration of sodium iodide varied from 0.55 to 2.07. Ostwald coefficients decreased with addition of sodium iodide with the Sechenov constant ranging from 0.119 to 0.129. Addition of sodium iodide to *N,N*-dimethylformamide also reduced the Ostwald coefficient of carbon dioxide. The Sechenov constant for a solution saturated with sodium iodide, calculated from the solubility measurements, is 0.199. These measurements appear to be reliable but need confirmation.

Rosenthal (8) also investigated the effect of adding octadecanoic acid to 2-propanone and to *N,N*-dimethylformamide. The Ostwald coefficient for solutions in *N,N*-dimethylformamide passed through a maximum with increasing concentration of octadecanoic acid. Perhaps this behaviour was due to an increasing formation of micelles as the concentration of octadecanoic acid was increased. Addition of octadecanoic acid caused a decrease in the Ostwald coefficient for dissolution in 2-propanone at the two concentrations of acid which were studied. Addition of a mole fraction of 0.00506 of acid to 2-propanone caused the Ostwald coefficient to fall from 6.88 to 5.01. Further addition to give a mole fraction of acid of 0.00805 caused a much smaller fall in the Ostwald coefficient to 4.93. These systems would bear re-investigation.

Kosakewitsch (9) measured solubility at 288.15 K and a partial pressure of 101.3 kPa in methanol containing various proportions of lithium chloride, bromide or iodide or sodium iodide. Maximum mole ratios of salt to

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Mixed Solvents 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>methanol were LiCl:0.0917, LiBr:0.1031, LiI:0.0241, NaI:0.0835. The solubility in solutions of these salts in ethanol at 293.15 K and 101.3 kPa was also measured. Maximum mole ratios in this case were LiCl:0.1511, LiBr:0.0642, LiI:0.1040, NaI:0.0844. The evaluator has found that plots of ln(mole ratio solubility) against the mole ratio concentration of salt in methanol are close to straight lines. Under these conditions solubility in methanol approximates to a Sechenov type relationship i.e.</p> $\ln(\text{mole ratio CO}_2/\text{CH}_3\text{OH}) = A - B(\text{mole ratio MX}/\text{CH}_3\text{OH})$ <p>(MX = salt; A & B are constants)</p> <p>Addition of salt decreases the solubility of the gas in each case and there is negligible differences between the effects of the different salts. The value of A is -4.798. The average value of B is 7.368.</p> <p>Solubility in ethanol follows similar relationships to a maximum mole ratio of salt to ethanol of about 0.06. The value of A is -4.869. The value of B is about 6.173 for LiCl, LiBr and NaI but is about 8.193 for LiI. The values of B decrease at higher concentrations of salt.</p> <p>No other measurements of the solubility of carbon dioxide in solutions of salts in methanol or ethanol are available to the evaluator for a direct comparison. However there is good agreement between the author's values of solubility in pure methanol and in pure ethanol and values reported by other workers. The mole fraction solubility in methanol at 288.15 K from Kosakewitsch's work is 0.00818. The value from the smoothing equation given by the evaluator on page 128 is 0.0080 ± 0.0014. The mole fraction solubility in ethanol at 293.15 K from the work is 0.00762 compared with a value of 0.00789 ± 0.00002 from the equation for solubility in ethanol on page 128.</p>

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:			
A sample of the mixture under test was placed in an absorption bulb fitted with a magnetic stirrer. The mixture was frozen and degassed under vacuum. The bulb was then maintained at the required temperature by thermostatic control. The vapor pressure of the solvent mixture was measured. Appropriate taps were then opened to allow carbon dioxide from one or more bulbs of known volume to come into contact with the sample. The pressure of gas before and after coming into contact with the liquid was measured with mercury manometers. Allowance was made for the volumes of various connecting tubes in the calculation of the quantity of carbon dioxide absorbed by the liquid.	2. distilled; purity checked by measurement of the refractive index which differed by less than 0.1% from the value quoted in the literature.			
	3. fractionally distilled under vacuum; refractive indices differed by less than 0.1% from literature values.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: An indirect method (1) was used in which the absorption rate of carbon dioxide into the mixed solvent was measured as a function of time. It was assumed that the film-theory model of the gas absorption process applied. A plot of ln (absorption rate) <i>vs.</i> time is linear. The slope is a function of the diffusion coefficient and the intercept is a function of both the diffusion coefficient and the solubility. A diaphragm cell with interfacial area 5.81 cm ² and lower compartment volume for the liquid was 53.5 cm ³ . The diaphragm was Millipore Teflon of mean pore size 10.0 μm, thickness 125 ± 15 μm, and porosity 0.68. The liquid was stirred at a constant rate of 1.33 rotations s ⁻¹ . The solutions were prepared and then degassed by refluxing for five hours. Their compositions were determined by density or refractive index. The CO ₂ was presat. with solvent vap.		SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Source not identified. From cylinder. (2, 3) Benzene and tetrachloromethane. It was stated that the chemicals were of special grade.		
		ESTIMATED ERROR: δ T/K = ± 0.1 δ c ₁ /c ₁ = ± 0.05 - 0.10 (compiler).

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
An indirect method (1) was used in which the absorption rate of carbon dioxide into the mixed solvent was measured as a function of time.		(1) Carbon dioxide. Source not identified. From cylinder.		
It was assumed that the film-theory model of the gas absorption process applied. A plot of ln (absorption rate) vs. time is linear. The slope is a function of the diffusion coefficient and the intercept is a function of both the diffusion coefficient and the solubility.		(2, 3) Benzene and 1-propanol.		
A diaphragm cell with interfacial area 5.81 cm ² and lower compartment volume for the liquid was 53.5 cm ³ . The diaphragm was Millipore Teflon of mean pore size 10.0 μm, thickness 125 ± 15 μm, and porosity 0.68. The liquid was stirred at a constant rate of 1.33 rotations s ⁻¹ .		It was stated that the chemicals were of special grade.		
The solutions were prepared and then degassed by refluxing for five hours. Their compositions were determined by density or refractive index. The CO ₂ was presat. with solvent vap.		ESTIMATED ERROR:		
		δ T/K = ± 0.1 δ c ₁ /c ₁ = ± 0.05 - 0.10 (compiler).

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).		(1) Carbon dioxide. Air Products and Chemicals, Inc. Minimum purity 99.8 mole per cent.	
Degassing. Up to 500 cm ³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid nitrogen trap until the permanent gas residual pressure drops to 5 microns.		(2) Cephalin. Nutritional Biochemicals Corp. Homostatic phosphatide obtained from bovine brain tissue, used as received.	
Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.		(3) Benzene. J. T. Baker Analyzed Reagent Grade. 99.9 mole per cent, thiophene free.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Carbon dioxide was bubbled through the alcohol or alcohol and halide for two to four days. A portion of the saturated solution of gas was then added to CO ₂ -free water containing a measured quantity of sodium hydroxide. The mixture of sodium hydroxide and carbonate was then titrated against hydrochloric acid using phenolphthalein as indicator.		1. Carbon dioxide was prepared by the action of hydrochloric acid on calcium carbonate. The gas was purified and dried by the usual methods.	
Separate portions of the original solution of gas were analysed for halide content by the Volhard method.		2. The alcohol was said to be free from water.	
Solubilities were corrected to a partial pressure of carbon dioxide of 101.3 kPa.		3. No information.

CRITICAL EVALUATION:

Solubility of Carbon Dioxide in Mineral Oils

Various groups have measured the solubility of carbon dioxide in petroleum fractions. Precise comparison between different sets of data is not possible because of the differences in chemical nature of the materials under test. A high proportion of cyclic hydrocarbons is likely to lower the solubility of carbon dioxide. In some cases average relative molecular masses have been stated and these enable semi-quantitative comparison of solubility data. Many of the solubility values have been measured at 293.15 K. Bunsen coefficients at this temperature range from 0.76 to 1.54 and mole fraction solubilities from 0.014 to 0.028. At this temperature there is a general tendency for an increase in Bunsen coefficient to be associated with a decrease in the relative molecular mass (see Table 1). Data published by Luther and Hiemenz for a sample of kerosene are contrary to this trend. The Bunsen coefficient is low for an oil of relative molecular mass of 405. This may be due to the large proportion of cyclic hydrocarbons stated to be present. A summary of the available data for mineral oils is shown in Table 1.

RMM = average relative molecular mass (The nature of the average is not usually stated; i.e. whether mass average or number average)

* density at 293.15 K except where indicated.

¹ 288.15 K

² 298.15 K

³ 341.45 K

COMPONENTS:			ORIGINAL MEASUREMENTS:			
1. Carbon dioxide; CO ₂ ; [124-38-9]			Luther, H.; Hiemenz, W.			
2. Paraffin oil			Chem. Ing. Tech. 1957, 29, 530-535.			
VARIABLES:			PREPARED BY:			
T/K = 293.15-355.15 P/kPa = 0-80 kPa			P.G.T. Fogg			
EXPERIMENTAL VALUES:						
T/K	Concentration of CO ₂ * /mol m ⁻³		Ostwald coeff. L	Henry's law constant		Mole fraction solubility at 101.3 bar
	liquid	gas		/atm	/kPa**	
293.15	4.67	5.72	0.816	57.2±4.2	5800±430	0.0175
314.15	3.89	5.30	0.734			
334.65	3.39	5.02	0.675			
355.15	3.05	4.72	0.646			
At 293.15 K the mole fraction solubility was shown to be proportional to the partial pressure of carbon dioxide to a pressure of at least 600 Torr (80 kPa).						
* concentrations correspond to a partial pressure of carbon dioxide of about 13 kPa.						
** calculated by the compiler.						
AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:			
A spectroscopic method was used. The gas and solution under test was circulated through cuvettes. The concentration of carbon dioxide in the gas and liquid phases were calculated from the integrated extinction coefficient due to the infra-red band at 2350 cm ⁻¹ .			1. from a cylinder; purified by the usual methods.			
			2. contained about 30% cyclic naphthenes and 70% slightly branched alkanes; d ₄ ²⁰ = 0.8795; relative molecular mass = 405.			
			ESTIMATED ERROR:			
			δL ≤ ±7.5% (authors)

AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:
The solvent was boiled to remove any gases in solution and was then introduced into the absorption vessel without coming into contact with the air. The volume of carbon dioxide absorbed by the liquid from gas buret was then measured. The composition of the solution after equilibrium was attained was measured by chemical analysis. This enabled a check to be made of solubility as calculated from the volume of gas absorbed. The absorption vessel and the gas buret were kept at constant temperature by circulation of water from a thermostat bath.	1. Carbon dioxide - 99.99% pure, from a cylinder supplied by Matheson Chemical Company.
	2. Ramol 350 supplied by Sherwood Refining Company, Detroit, Mich. USA.
	ESTIMATED ERROR:
	δT/K = ±0.1 Solubility measurements reproducible to about ±0.5% (authors).

AUXILIARY INFORMATION																										
METHOD/APPARATUS/PROCEDURE: The apparatus consists of an 180 cm ³ absorption bottle connected to a 100 cm ³ gas buret. The absorption bottle sets in a thermostat, which is attached to a shaking machine. A weighed sample of oil is introduced into the absorption vessel. The sample is degassed by vacuum taking care to avoid excessive foaming. The gas is brought into the system. An initial buret reading taken, and the shaker is started and reading taken every 5 minutes until 2 or 3 constant readings are obtained.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. No information. (2) Mineral oil. A Pennsylvania base oil, 96 per cent saturated hydrocarbons, and distilling between 300 and 400°C. Density at 25°C = 0.840 and at 80°C = 0.800 g cm ⁻³ . As a commercial product the oil is known as "Wemco A". ESTIMATED ERROR: REFERENCES:

METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:																																												
The apparatus was based upon the equilibrium adsorption apparatus described by Brunauer, Emmett and Teller. Gas was circulated through the vessel containing wax. Pressures were measured with a mercury manometer. Measured quantities of carbon dioxide were delivered to the system from two calibrated burets. A period of 20-60 minutes was allowed for the system to reach equilibrium after each addition of gas.			1. Obtained by heating NaHCO ₃ ; contained 0.1% N ₂ , 0.1% O ₂ , 3.4% CO.

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Animal and Vegetable Oils and Fats 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
<p>CRITICAL EVALUATION:</p> <p>Solubility of carbon dioxide in animal and vegetable oils and fats.</p> <p>There have been several measurements (1-6) of the solubility of carbon dioxide in olive oil at a partial pressure of 101.3 kPa. The most reliable are probably those carried out by Yeh and Petersen (1) from 298.2 K to 318.2 K and by Battino <i>et al.</i> (2) from 298.0 K to 327.9 K. In both cases the oil was carefully degassed before absorption of carbon dioxide. Values of mole fraction solubility from the two sources agree to within 2%. The recommended smoothing equation, based on these two sets of data, is given below.</p> $\ln x_{\text{CO}_2} = -88.009 + 4996.8/(T/K) + 11.9998 \ln(T/K)$ <p>temperature range = 298.0-327.9 K standard deviation in x_{CO_2} = 0.00023</p> <p>The average thermodynamic values for the transfer of one mole of carbon dioxide at a partial pressure of 101.3 kPa to a hypothetical solution of unit mole fraction concentration are</p> $\Delta H^\circ/\text{J mol}^{-1} = -10479$ $\Delta S^\circ/\text{J mol}^{-1} \text{ K}^{-1} = -59.1$ <p>The equation for the Bunsen coefficient, α, based on data from the two sources is</p> $\ln \alpha = -3.0329 + 1328.0/(T/K) - 0.20002 \ln(T/K)$ <p>temperature range = 298.0-327.9 K standard deviation in α = 0.029</p> <p>Yeh and Petersen (1) measured the solubilities of carbon dioxide in dog fat, rat-pooled fat, and two samples of human fat over the temperature range 298.2-318.2 K. In all cases Bunsen coefficients were within 1.6% of the values which they found for olive oil at the same temperatures. Nichols (7) also measured solubility in dog fat, rat-pooled fat and human fat. Values of Bunsen coefficients from these measurements were close to each other but about 10% lower than Yeh and Peterson's values.</p> <p>Tomoto and Kusano (5) measured solubility in olive oil, linseed oil and soybean oil. The data which they published are close to those in an earlier paper by Tomoto (4). They found that Bunsen coefficients at 293.2 K and 323.2 K for solution in linseed oil were greater than the coefficients for olive oil. Bunsen coefficients for soybean oil were less than for olive oil. Schmidt-Nielsen's data (3) also indicate that the Bunsen coefficient for carbon dioxide in linseed oil at 293.2 K is greater than that for olive oil at this temperature. However Tomoto's and Schmidt-Nielsen's values of Bunsen coefficients for both linseed oil and olive oil are lower than Bunsen coefficients for olive oil from data published by Yeh and Petersen and by Battino <i>et al.</i> which are recommended above.</p> <p>Schmidt-Nielsen (3) also found that the solubility of carbon dioxide ($\text{cm}^3 \text{ g}^{-1}$) in cod-liver oil and in herring oil was greater than in olive oil. Further work is needed to establish the relative solubilities in these solvents.</p> <p>Vibrans (8) measured solubility in cottonseed oil at about 298 and 318 K. Temperature control was poor but averaged values of Bunsen coefficients are close to those for olive oil. The average value for 296-299 K was found to be 1.34 ± 0.04 compared with a value for olive oil at 298.2 K of 1.3565 (Yeh and Petersen). The average value for 318 K was 1.012 ± 0.029 compared with 1.0150 for olive oil (Yeh and Petesen). Vibrans also found</p>	

<p>COMPONENTS:</p> <ol style="list-style-type: none"> 1. Carbon dioxide; CO₂; [124-38-9] 2. Animal and Vegetable Oils and Fats 	<p>EVALUATOR:</p> <p>Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.</p> <p>July 1991</p>
---	--

CRITICAL EVALUATION:

that the Bunsen coefficient for dissolution in steam rendered lard at 318 K was 1.014 ± 0.012 , close to the value of 1.012 for cottonseed oil.

Schaffer and Haller (9) measured solubility in cottonseed oil at 313.2 K. Their value for the Bunsen coefficient was 0.876 which is not in accord with values reported by Vibrans. Schaffler and Haller also reported Bunsen coefficients for solubility in lard at 313.2 K and in butter oil at 313.2 K and 333.15 K. The value for lard is, in this case, slightly lower than the value given by Vibrans (Schaffer at 313.2 K: 1.003; Vibrans at about 318 K: 1.014). The Bunsen coefficients for dissolution in butter oil were greater than values for olive oil reported by Yeh and Petersen (1) and by Battino *et al.*(2).

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a thermostated absorption flask, a gas reservoir, and a manometer and leveling bulb system. The oil is placed in the absorption flask and both are weighed, the system is heated to 80°C and evacuated for six hours to degass the solvent. The gas is admitted to the system. The oil is stirred by a magnetic stirrer until equilibrium is attained. The flask and contents are disconnected from the system and weighed. The amount of gas absorbed is calculated from the gain in weight. The loss of oil due to evaporation during the degassing is considered negligible. <p>The Bunsen coefficients are the average of three measurements. The Ostwald coefficients were fitted by the method of least squares to the equation $\log L = A/T + B$ by the authors. The same line fitted olive oil and the fats. From the slope and intercept they obtained</p> $\Delta H^\circ/cal\ mol^{-1} = -1217 \pm 30 \text{ and } \Delta S^\circ/cal\ K^{-1}\ mol^{-1} = -8.5 \pm 0.1.$ <p>The thermodynamic values are for the standard state transfer of one mole of carbon dioxide from the gas phase at a concentration of one mole dm^{-3} to the solution at a concentration of one mole dm^{-3}. See the evaluation of the carbon dioxide + olive oil system for the thermodynamic values of the standard state transfer on one mole of carbon dioxide from the gas phase at a partial pressure of one atm to the hypothetical unit mole fraction solution.</p> <p>Smoothed Data: For use between 298.15 and 318.15 K.</p> $\ln x_1 = -7.1013 + 12.5711/(T/100\ K)$ <p>The standard error about the regression line is 1.15×10^{-4}. For more information see the evaluation.</p>																					
AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: <p>Oil was dried and degassed by stirring under vacuum at 80°C for about 12 hr. A 50 ml. sample was placed in an absorption flask attached to a Geffken gas buret (1). The oil was constantly stirred and equilibrated with increments of gas until no change was observed in a differential oil manometer for $\frac{1}{2}$ hr. Difference between initial and final buret readings indicated amount of gas absorbed. Absorption at successively lower temperatures was determined. The authors also measured the viscosity and surface tension of the liquid.</p>	SOURCE AND PURITY OF MATERIALS: <p>(1) Carbon dioxide. Matheson Co., Inc. AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:				SOURCE AND PURITY OF MATERIALS:		
Fatty tissue homogenized with sand at 30-35 °C in a buffer solution at pH 4.0 or, in the case of one rat sample, at pH 7.40. Fat removed by centrifuging. Dry air mixed with 23.5-24.9% CO ₂ passed for 2.5 to 5 h through samples of volume 3-5 cm ³ . Solutions then analysed by use of a van Slyke apparatus. Concentrations of CO ₂ corrected to a partial pressure of 101.3 kPa.				1. No information		
				2. Depot fat from the following sources: Dog - perirenal and subcutaneous fat from an adult mongrel dog 2 h after death by exsanguination under anesthesia. Rat - perirenal, subcutaneous and retroperitoneal fat from six 200-day old Wistar rats killed by a blow on the head followed by exsanguination. Samples pooled and divided in two parts, A and B. Human - omental fat from an 86-year old woman 5 h after death.		
				Negligable water content - no loss of weight from any sample during 48 h in a dessicator		
				ESTIMATED ERROR:		
				See above

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The apparatus consists of a thermostated absorption flask, a gas reservoir, and a manometer and leveling bulb system. The oil is placed in the absorption flask and both are weighed, the system is heated to 80°C and evacuated for six hours to degass the solvent. The gas is admitted to the system. The oil is stirred by a magnetic stirrer until equilibrium is attained. The flask and contents are disconnected from the system and weighed. The amount of gas absorbed is calculated from the gain in weight. The loss of oil due to evaporation during the degassing is considered negligible.			SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Commercial cylinder. Passed through the purification train: stannous chloride, NaHCO ₃ , CuSO ₄ , conc. H ₂ SO ₄ , hot copper, and P ₂ O ₅ . (2) Linseed oil. Iodine value 175, acid value 0.32, density ρ/g cm ⁻³ = 0.9232, 0.9163, and 0.9096 at 30, 40, and 50°C, respectively.

CRITICAL EVALUATION:

Solubility of carbon dioxide in polymeric materials

The solubility constant for dissolution of gas in a polymer has been defined (1) as

volume of gas absorbed (reduced to 1 atm, 273.15 K)

—————
volume of polymer × pressure of gas/atm

Solubility in different samples of polyethylene has been measured by Michaels and Bixler (1) at 273.2 K; 101.3 kPa. Values of the solubility constant were unaffected by the magnitude of the number average relative molecular mass. Ash *et al.* (2) measured solubility in a single sample of polyethylene at 313.2–333.2 K. Values of the solubility constant are consistent with a value given by Michaels and Bizler for polyethylene tested at 273.2 K, if error limits are taken into account.

Solubility in orientated polyethylene terephthalate having an amorphous volume fraction of 0.49 has been measured by Vieth *et al.* (3) from 5.5 kPa to 130.5 kPa at 298.2 K and 313.2 K. The authors showed that the measurements were consistent with earlier measurements of solubility in samples of unorientated material having amorphous volume fractions of 0.58 and 1, reported by Michaels *et al.* (4).

Michaels and Bixler (1) measured the dissolution of carbon dioxide in unvulcanised smoked sheet rubber. The solubility constant for this material at 273.2 K was found to be 0.95 atm⁻¹. This value may be compared with a solubility constant for unvulcanised smoked sheet rubber of 1.02 atm⁻¹ at 293 K which was reported by Venable and Fuwa (5). Venable and Fuwa also reported the solubility in other samples of rubber.

Solubility in polyvinyl acetate has been measured by Liu and Prausnitz (6) and in Nylon 11 by Ash *et al.* (2). Solubility in hydrogenated polybutadiene was measured by Michaels and Bixler. There is no reason to doubt the reliability of these sets of measurements but no other work on these systems is available to the evaluator for comparison.

VARIABLES:	PREPARED BY:	
P/kPa = 101.3 T/K = 273.15	P.G.T. Fogg	
EXPERIMENTAL VALUES:		
Polymer	Solubility constant, <i>k'</i> /atm ⁻¹	Volume fraction of amorphous polymer, α
Polyethylene	0.451 ± 0.023	0.22-0.65
Hydrogenated polybutadiene	0.577	0.71
Natural rubber	0.95	1
The solubility constant, <i>k</i> , is defined as the ratio of volume of gas absorbed at a partial pressure of gas of 1 atm to volume of polymer, corrected to 273.15 K and 1 atm, . The authors state that the value of <i>k</i> depends upon the volume fraction of amorphous polymer in the sample. Constants <i>k'</i> given above refer to hypothetical amorphous polymers and are related to <i>k</i> by the equation		
$k' = \alpha k$		
where α is the volume fraction of amorphous polymer.		
The authors measured the solubility of thirteen different gases in three different polyethylenes having different number average relative molecular mass. These polyethylenes were <i>Grex</i> , <i>Alathon 14</i> and <i>Epolene C</i> . These three polymers gave no significant differences between values of <i>k'</i> for a particular gas. The hydrogenated polybutadiene was a sample of <i>Hydropol</i> .		
AUXILIARY INFORMATION		
METHOD/APPARATUS/PROCEDURE:		
Two methods of measuring solubility are mentioned. One method, used for samples of polyethylene, involved equilibrating the gas under test at a pressure of about 1 atm with pellets of the polymer. Gas in the voids was then quickly pumped off during a period of about 10 secs. Gas which subsequently diffused from the polymer was taken to be dissolved gas. It was estimated that about 5% of the dissolved gas was lost during the rapid evacuation period.		
A second method was the time lag method based upon work by Barrer (1). Gas at pressures from 5 mmHg to 800 mmHg was brought into contact with a film of polymer in an evacuated section of the apparatus. The build up of gas at the other side of the film was monitored. this method was used for all the polymers under test with the exception of <i>Epolene C</i> .		
SOURCE AND PURITY OF MATERIALS:

<p>EXPERIMENTAL VALUES:</p> <p>Absorption of carbon dioxide in various samples of polyethylene terephthalate of different degrees of crystallinity and thicknesses were measured by time-lag solubility measurements and by static measurements. Absorption isotherms for glassy amorphous polymer were explained by postulating that absorption took place by two concurrent mechanisms. One mechanism involved the filling of voids and the other an ordinary dissolution process. The shape of the isotherms was explained by assuming that the filling of the voids was consistent with a Langmuir mechanism and the dissolution was consistent with Henry's law.</p> <p>C^* = volume of gas, reduced to 273.15 K and 101.3 kPa, taken up by one cm³ of amorphous polymer.</p> <p>C_D^* = reduced volume of gas absorbed by a dissolution process</p> <p>C_H^* = reduced volume of gas absorbed by a void-filling process</p> <p>$C_H^{*'} =$ reduced volume of gas absorbed by saturation of voids</p> <p>b = a constant</p> <p>k_D^* = solubility constant for dissolution defined as</p> $\frac{\text{reduced volume of gas dissolved}}{\text{pressure} \times (\text{volume of amorphous polymer})}$ <p>k^* = solubility constant for adsorption of gas defined as the value at low pressures of</p> $\frac{\text{reduced volume of gas adsorbed in voids and by dissolution}}{\text{pressure} \times (\text{volume of amorphous polymer})}$ <p>At a pressure of P it follows that</p> $C^* = C_H^* + C_D^* \quad (1)$ $= C_H^{*'}bP/(1+bP) + k_D^*P \quad (2)$ <p>At low pressures this equation may be written</p> $C^* = (C_H^{*'}b + k_D^*)P \quad (3)$ $= k^*P$ <p>At high pressures when the microvoids are all filled equation (2) may be written</p> $C^* = C_H^{*'} + k_D^*P \quad (4)$ <p>The variation in absorption of gas at high pressure from by time-lag solubility measurements gave a value for the constant k_D^* of 0.38 atm⁻¹ at 298.15 K. Absorption of gas at low pressures at 298.15K measured by a static method fitted the equation</p> $C^* = \frac{2.33P/\text{atm}}{1 + 0.44P/\text{atm}} + 0.38P/\text{atm}$ $k^* = 2.33 + 0.38 = 2.71 \text{ atm}^{-1}$ <p>Samples of partially crystalline polymer with an amorphous volume fraction less than 1 absorbed less gas. The authors interpreted this by assuming that the crystalline fraction could only take up gas in the microvoids and not by a dissolution process.</p>	

Values of the solubility constant for the amorphous polymer, k^* , at other temperatures were displayed on a small scale graph. Approximate values for the amorphous polymer from the graph are as follows

T/K solubility constant for
amorphous polymer, k^*/atm^{-1}

298	2.71 [†]
320	1.42
337	0.89
342	0.63

Glass transition zone approximately 355-368 K

s - static measurements; t - time-lag measurements

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Low pressure static absorption measurements were carried at pressures up to about 170 kPa in glass apparatus using sheets of polymer film. The system was evacuated and a measured quantity of gas admitted. The amount of gas absorbed was calculated from the initial and final pressures.

Time-lag solubility measurements were carried out to pressures of about 1240 kPa using apparatus similar to that described earlier. (1,2).

SOURCE AND PURITY OF MATERIALS:

1. Dried with CaSO_4 ; minimum purity 99.5%

2. Amorphous polyethylene terephthalate supplied by the Mylar laboratory of E.I. du Pont de Nemours & Co. Number average relative molecular mass 15-20 000. Crystalline samples prepared by annealing the amorphous polymer at 120°C to 150°C. Densities of samples were measured with density gradient columns and the amorphous volume fraction determined assuming that the fully crystalline polymer has a density of 1.455 g cm⁻³. (3)

ESTIMATED ERROR:

Static measurements - precision limits $\pm 3.5\%$ at the 95% confidence level.
Time-lag measurements - precision limits of $\pm 10\%$ (authors)

Henry's law constant, H, is defined as:			
$H = \lim_{w \rightarrow 0} \left[\frac{f}{w} \right]$			
where f is the fugacity of the carbon dioxide and w the weight fraction of carbon dioxide in the polymer.			
The polymer had a number average relative molecular mass of 8.34 × 10 ⁴ .			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
Solubilities were measured by gas-liquid chromatography using helium as carrier gas and Chromosorb as support material. A weighed quantity of poly(vinyl acetate) was dissolved in a mixture of methanol and 1,2-dichloroethane at 80°C. This was then mixed with a weighed and preheated quantity of the support. The mixture was then heated in an oven until methanol and 1,2-dichloroethane had evaporated. and subsequently used in a steel chromatography column. The dead time of a chromatogram was found by injecting nitrogen. Retention volumes for carbon dioxide were found for various ratios of polymer to support material. This enabled correction to be made for surface adsorption of carbon dioxide. Henry's constants were calculated from the corrected retention volumes. Additional correction was made for the solubility of nitrogen.	1. Supplied by Matheson Gas Products; purity > 99%

AUXILIARY INFORMATION									
METHOD/APPARATUS/PROCEDURE: The gas at a known temperature and pressure was allowed to reach equilibrium with a sample of the polymer. The gas phase was then flushed out by mercury and the dissolved gas allowed to desorb into a previously evacuated vessel of known volume. The pressure of the desorbed gas was measured with a McLeod gauge. The temperature of the desorbed gas was also measured and the quantity of gas calculated from its volume, pressure and temperature. Correction was made for the absorbed gas lost during the flushing process. Measurements were made at various initial pressures of gas. The maximum pressure was not stated but measurements on the solubility of gases in polyethylene which are reported in the same paper were made to a maximum pressure of about 25 cmHg (33 kPa).	SOURCE AND PURITY OF MATERIALS: 1. Spectrally pure sample supplied by British Oxygen Company. 2. From laminated tubing made by Messrs. Griflex Ltd. ESTIMATED ERROR: $\delta T/K < \pm 0.1$ $\delta(\text{solubility constant}) = \pm 2\%$ (authors) REFERENCES:								

COMPONENTS:	EVALUATOR:
1. Carbon dioxide; CO ₂ ; [124-38-9]	Peter G.T. Fogg, School of Applied Chemistry, Polytechnic of North London, Holloway Road, London, N7 8DB, U.K.
2. Liquid Gases	July 1991

CRITICAL EVALUATION:

Solubility of solid carbon dioxide in liquid gases.

The solubility of solid carbon dioxide in liquid oxygen was measured by Amamchyan *et al.*(1) from 77 K to 95 K and by Rest *et al.*(2) from 89.5 K to 118.5 K. Equations for mole fraction solubility over the temperature ranges of measurement were given by each group of authors. Error limits in x_{CO_2} were quoted as $\pm 15\text{-}20\%$ by Amamchyan and as $\pm 21\%$ by Rest. The two equations give the same value of x_{CO_2} at 87.7 K. Values for x_{CO_2} at 95 K from the two equations are as follows

Amamchyan <i>et al.</i>	10.75 ± 1.61 to 2.15×10^{-6}
Rest <i>et al.</i>	$8.00 \pm 1.68 \times 10^{-6}$

The limits of error for the two values overlap. The two equations are therefore consistent with each other, within the limits of error given by the authors.

Rest *et al.*(2) measured the solubility of solid carbon dioxide in liquid argon from 87.9 K to 120.5 K and published an equation for the variation of mole fraction solubility with temperature. Preston *et al.*(3) also measured the solubility in argon at 109.0 K and 115.9 K. Mole fraction solubility at these two temperatures from the two sources are as follows

	109.0 K	115.9 K
Rest <i>et al.</i>	$2.25 \pm 0.47 \times 10^{-5}$	$4.27 \pm 0.90 \times 10^{-5}$
Preston <i>et al.</i>	$7.97 \pm 3.67 \times 10^{-5}$	$20.59 \pm 2.26 \times 10^{-5}$

The two sets of measurements are not compatible.

Rest *et al.*(2) also measured the solubility of solid carbon dioxide in liquid nitrogen from 77.7 K to 117 K. No other measurements on this system are available for comparison.

Chang *et al.*(4) measured the solubility in liquid nitrogen oxide at partial pressures of carbon dioxide from 17.2 kPa to 67.8 kPa at 262.2 K to 293.2 K. Values of mole fraction solubility are close to 'ideal' or reference values from Raoult's law. Solubility of carbon dioxide gas in liquid chlorine was measured by Krieve and Mason (5) at partial pressures of carbon dioxide to 66.3 kPa at 273.2 K and 298.2 K. In this case experimental values of mole fraction solubility fall much lower than the reference values from Raoult's law. A selection of mole fraction solubilities in the two gases is given below.

Solvent	T/K	P_{CO_2} /kPa	x_{CO_2}	R.L.
liquid nitrogen oxide	262.15	58.49	0.02103	0.0228
	273.15	34.11	0.01018	0.0098
	293.15	63.07	0.01265	0.0110
liquid chlorine	273.15	78.2	0.0106	0.0225
		111	0.01593	0.0319
	298.15	111	0.00976	0.0173

(R.L. = reference value from Raoult's law)

The measurements on both systems are self-consistent but no other data on either system are available to the evaluator for comparison.

The solubilities of solid carbon dioxide in liquid methane, ethane, propane, butane, 2-methylpropane, ethene and propene have been measured. The data which are available have been discussed earlier (pages 1,8,10).

EXPERIMENTAL VALUES: <p>The solubility of solid carbon dioxide in liquid oxygen was measured at six temperatures in the range 77 K to about 95 K. The following equation was given for the mole fraction solubility in this temperature range:</p> $\log_{10} x_{\text{CO}_2} = 2.40 - 700/(T/K)$ <p>The mole fraction solubility at 90 K was given as $4.3 \pm 0.5 \times 10^{-6}$</p>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: Liquid oxygen and solid carbon dioxide were contained in an optical cryostat described previously (1,2). The solubility was calculated from optical density as measured by IKS-16 and IKS-21 spectrometers. The liquid was stirred vigorously before each measurement and then allowed to stand until the absorption band due to suspended solid carbon dioxide had disappeared. Measurements with step-wise increase in the temperature differed by less than 10% from measurements when the temperature was decreasing. At a particular temperature the pressure was equal to the vapor pressure of liquid oxygen, nitrogen or argon.			
AUXILIARY INFORMATION			
METHOD / APPARATUS / PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
Solid carbon dioxide was added to liquid oxygen, nitrogen or argon. Large particles of carbon dioxide were filtered off. The liquid containing carbon dioxide in solution and in suspension was introduced into a variable pressure infra-red absorption cell surrounded by a thermal shield chamber also containing liquid oxygen, nitrogen or argon. Temperature was varied by applying pressure to the solution from a gas cylinder or by supplying heat from a heating element at the bottom of the cell. Infra-red spectra were recorded at intervals until equilibrium was reached at a particular temperature. Concentrations of carbon dioxide were calculated from the intensities of bands due to carbon dioxide in solution but not due to carbon dioxide in suspension.	1. commercial sample of specified purity 99.999% 2. AUXILIARY INFORMATION																			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																		
Solubilities were measured in a vacuum cryostat held in a bath of liquid nitrogen. The temperature of the cryostat could be controlled by electric heating. Temperatures were measured by a calibrated copper-constantin thermocouple. Vapor from the cell was pumped from the top of the cell, cooled, passed into the base of the cell and bubbled through the liquid. This speeded up the attainment of equilibrium. Samples of liquid from the cell were vaporized and analyzed by gas chromatography. Full details of the apparatus have been given by Preston (2) and Funk (3).	1. Supplied by Matheson Co.; purity 99.8% 2. Supplied by Matheson Co.; purity 99.97% (methane), 99.995% (argon).

† partial pressure of carbon dioxide.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Measured amount of gas added to cell of known volume. Composition of liquid determined from knowledge of total amounts of chlorine and carbon dioxide and assuming Raoult's law followed by chlorine in vapor.		1. Matheson Co. sample, pure grade.	
		2. Commercial sample, fractionally distilled.	
		ESTIMATED ERROR:	
		δT/K = ±0.1; δP/10 ⁵ Pa = ±0.5%;	
		δx _{CO₂} = ±0.001 (estimated by compiler).	
		REFERENCES:	

SYSTEM INDEX

Page numbers preceded by E refer to evaluation texts whereas page numbers not preceded by E refer to compiled tables. Compounds are named as in Chemical Abstracts indexes (toluene appears under Benzene, methyl-).

Acetaldehyde	E178, E179, 204
Acetamide, <i>N,N</i> -dimethyl- (ternary)	E384, 392
Acetic acid	E179, E180, E187, E188, 218, 219
Acetic acid anhydride	E180, E187, 223
Acetic acid, 2-[2-(2-butoxyethoxy)ethoxy]ethanol ester	E182, E183, 234
Acetic acid, butyl ester	198
Acetic acid, ethenyl ester homopolymer	E448, 455
Acetic acid, ethyl ester	109, E180, E187, E188, 198, 227, 228
Acetic acid, 2-[2-(2-methoxyethoxy)ethoxy]ethanol ester	E182, E183, 234
Acetic acid, methyl ester	E180, E187, 225, 226
Acetic acid, 2-methylpropyl ester	E180, E187, 230
Acetic acid, pentyl ester	E180, E187, E188, 219, 231
Acetic acid, propyl ester	E180, E187, 229
Adiponitrile	see hexanedinitrile
Amylacetate	see acetic acid, pentyl ester
Amyl alcohol	see 1-pentanol
Amyl bromide	see pentane, 1-bromo-
Aniline	see benzenamine
Argon	E457, 460, 461
2 <i>H</i> -Azepin-2-one, hexahydro-1-methyl-	E304, E306, 357
<i>p</i> -Azoxyphenetole	see diazene, bis(4-ethoxyphenyl)-1-oxide
Benzaldehyde	E179, E187, E188, 190, 205
Benzenamine	E302, E306, E307, 308-312
Benzenamine, 2-methyl-	E302, E306, 314
Benzenamine, 3-methyl-	E302, E306, 313
Benzene	E90, E94, E95, 96-98, 100-105, 114, E257, 397, 401, 408
Benzene (ternary)	E384, E385, 397, 400-404, 408, 409
Benzeneacetonitrile	E306, 355
Benzene, bromo-	E257, E259, E260, 295
Benzene, (chloromethyl)-	E258, E259, 300
Benzene, chloro-	E257, E259, E260, 295-297
Benzene, dimethyl-	E91, 86, 120
Benzene, 1,2-dimethyl-	E90, E91, E94, E95, 98, 114, 115
Benzene, 1,3-dimethyl-	E90, E91, E95, 105, 114, 116-118
Benzene, 1,4-dimethyl-	E90, E91, E94, E95, 99, 114, 119
Benzene, ethenyl- homopolymer (ternary)	E385, 408
Benzene, ethyl-	E91, E95, 99, 105
Benzene, hexafluoro-	E257, E259, E260, 299
Benzene, iodo-	E257, E259, 298
Benzenemethanol	E132, 172, 173
Benzenemethanol (ternary)	E384, 391
Benzene, methyl-	E90, E91, E94, E95, 98, 105-113, E258
Benzene, 1,1'-methylenebis-	E91, E94, E95, 122, 123
Benzene, 1,1-methylenebis(methyl)-	E91, E95, 124
Benzene, (1-methylethyl)-	E91, E95, 121

- Benzene, nitro- E304, E306, E307, 312, 349-351
 Benzene, trichloromethyl- E258, E259, 301
 Benzene, 1,2,4-trimethyl- E91, E95, 105
 Benzo-trichloride
 see benzene, trichloromethyl-
 Benzyl alcohol
 see benzenemethanol
 Benzyl cyanide
 see benzeneacetonitrile
 Benzyl chloride
 see benzene, (chloromethyl)-
 1,1-Bicyclohexyl E8, E13, 79, 80
 1,1'-Biphenyl, (1-methylethyl)- E92, 125
 1-Butanamine, 1,1,2,2,3,3,4,4,4-nonafluoro-*N,N*-bis-
 (nonafluorobutyl)- E302, E306, E307, 319, 320
 Butane E1, E13, 14-16
 Butane, 1,1,2,2,3,3,4,4-octafluoro-1,4-bis(1,2,2,2-tetra
 fluoro-1-(trifluoromethyl)ethoxy) E259, 291
 1,4-Butanediol E133, 176
 1,3-Butanediol (ternary) E384, 390
 2,3-Butanediol (ternary) E384, 390
 Butanoic acid E179, E180, E187, 220
 1-Butanol E130, E135, 146, 149,
 157
 2-Butanol E131, 149
 1-Butanol, 3-methyl- E131, E135, 137
 2-Butanone E178, 109, 196
 1-Butene E10, 83
 Butoxytriethyleneglycol acetate
 see Acetic acid,
 2-[2-(2-butoxyethoxy)ethoxy]ethanol ester
 Butter oil E431, 447
 Butyl oleate
 see 9-octadecenoic acid, butyl ester
 γ -Butyrolactone
 see furenone, dihydro-2(3*H*)-
 Carbon disulfide E359, E361, E362, 378-381
 Caroxin-D
 see butane, 1,1,2,2,3,3,4,4,-octafluoro-1,4-
 bis(1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy)-
 Caroxin-F
 see hexane, 1,1,1,2,2,3,3,4,4,5,5,6,6-tri-
 decafluoro-6-[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy]-
 Carvene
 see cyclohexene, 1-methyl-4-(1-methylethenyl)-
 Carvol
 see 2-cyclohexen-1-one, 2-methyl-5-(1-methylethenyl)-
 Cephalin (ternary) E385, 402
 Cellulose acetate (ternary) E385, 406, 407
 Chlorine E457, 463
 Chloroform
 see methane, trichloro-
 Cholest-5-en-3 β -ol (ternary) E385, 404, 405
 Cholesterol
 see cholest-5-en-3 β -ol
 Cod liver oil E430, 432
 Cottonseed oil E430, E431, 446, 447
m-Cresol
 see phenol, 3-methyl-
 Cumene
 see benzene, (1-methylethyl)-
 Cyclohexane E7, E9, E13, 64-72, E132, E257
 Cyclohexane, bromo- E257, E259, 293
 Cyclohexane, chloro- E257, E259, E260, 292
 Cyclohexane, 1,2-dimethyl-, *cis*- E8, E13, 76
 Cyclohexane, 1,2-dimethyl-, *trans*- E8, E13, 75
 Cyclohexane, 1,3-dimethyl-, *cis*- E8, 78
 Cyclohexane, 1,3-dimethyl-, *trans*- E8, 78
 Cyclohexane, 1,4-dimethyl-, *cis*- E8, 77

Cyclohexane, 1,4-dimethyl-, <i>trans</i> -	E8, 77
Cyclohexane, methyl-	E7, E9, E13, 72, 73
Cyclohexanol	E132, E135, 170, 171
Cyclohexanone	E178, E187, 201
Cyclohexanone, 2,6-dimethyl-	E178, E187, 202
Cyclohexene, 1-methyl-4-(1-methylethenyl)-	E10, E13, 89
2-Cyclohexen-1-one, 2-methyl-5-(1-methylethenyl)-	E178, 203
Cyclooctane	E8, E13, 74
Cyclopentane	E7, 63
Cyclopentanone	E178, E187, 200
Cyclopropane	E7, 62
Cyclotetrasiloxane, octamethyl-	E358, E361, E362, 371
Decalin	
see naphthalene, decahydro-	
Decane	E5, E9, E13, 27, 40-43
1-Decanol	E132, E135, 166, 167, 169
2-Decanone	197
3-Decanone	197
Diazene, bis(4-ethoxyphenyl)-1-oxide	E303, 328
α -Dichlorohydrin	
see 2-propanol, 1,3-dichloro-	
Diesel fuel	E418, 420
Diethylene glycol monomethyl ether	
see ethanol, 2-(2-methoxyethoxy)-	
Diethylene glycol dimethyl ether	
see ethane, 1,1'-oxybis(2-methoxy-	
Diglycolamine	
see ethanol, 2-(2-aminoethoxy)-	
<i>N,N</i> -Dimethylformamide	
see formamide, <i>N,N</i> -dimethyl-	
1,3-Dimethyl-1 <i>H</i> -pyrazole	
see 1 <i>H</i> -pyrazole, 1,3-dimethyl-	
Dimethylsulfoxide	
see methane, sulfinylbis-	
1,4-Dioxane	E181, E187, 198, 239, 240
1,3-Dioxolan-2-one	E179, 206
1,3-Dioxolan-2-one, 4-methyl-	E179, E187, E188, 86, 207-217, 330, 331
Diphenylmethane	
see benzene, 1,1'-methylenebis-	
Dipropylene glycol	
see propanol, oxybis-	
Ditolyl methane	
see benzene, 1,1-methylenebis(methyl-	
Dodecane	E5, E13, 30, 45, 46
1-Dodecanol	E128, E132, 168, 169
Eicosane	E6, E13, 58, 60, 61
Ethane	E1, E8, 14-16
Ethane (ternary)	E8, 85
Ethane, 1,2-dibromo-	E255, E259, E260, 268, 273-275
Ethane, 1,2-dichloro-	E255, E256, E259, E260, 264, 276
1,2-Ethanediol	E132, E135, 172, 174, 175, E182, E183
1,2-Ethanediol (ternary)	174, E384, 389
Ethane, 1,1'-oxybis-	E181-E183, E187, 236
Ethane, 1,1'-oxybis(2-methoxy-	E182, E183, 249
Ethane, 1,2-dichloro-1,1,2,2-tetrafluoro-	E256, E259, 271, 272
Ethane, 1,1,2-trichloro-1,2,2-trifluoro-	E255, E256, E259, 281
Ethanol	E128, E131, E135, 137, 138, 146-148, 150-153, E183
Ethanol (ternary)	E384, E386, 153, 416
Ethanol, 2-amino- (ternary)	E384, 387-395
Ethanol, 2-(2-aminoethoxy)- (ternary)	E384, 396
Ethanol, 2,2'-[1,2-ethanediylbis(oxy)]bis-	175, E181, E183, E187, 242, 243

- Ethanol, 2,2'-[1,2-ethanediylbis(oxy)]bis- (ternary) E384, 389
- Ethanol, 2-methoxy- E182, E183, E187, 246, 247
- Ethanol, 2-methoxy- (ternary) E384, 391
- Ethanol, 2-(2-methoxyethoxy)- E182, E183, 249
- Ethanol, 2-(2-methoxyethoxy)- (ternary) E384, 393
- Ethanol, 1,1-oxybis- (ternary) E384, 390
- Ethanol, 2,2'-[oxylbis(2,1-ethanediylloxy)]bis- (ternary) E384, 390
- Ethanol, 2-phenoxy- (ternary) E384, 393
- Ethene E8, E10, 83
- Ethene (ternary) E8, 85
- Ethene homopolymer E448, 449, 450
- Ethylene chloride see ethane, 1,2-dichloro-
- Ethylene glycol see 1,2-ethanediol
- Ethylene glycol monomethyl ether see ethanol, 2-methoxy-
- Ethylene glycol monophenyl ether see ethanol, 2-phenoxy-
- 1-Ethyl-3-methyl-1*H*-pyrazole see 1*H*-pyrazole, 1-ethyl-3-methyl-
- Ethyl oleate see 9-octadecenoic acid, ethyl ester
- Ethyl stearate see 9-octadecanoic acid, ethyl ester
- Ethyne (ternary) E178, 199, E303, E304, 348
- Eugenol see phenol, 2-methoxy-4-(2-propenyl)-
- Fat, dog E430, 438, 439
- Fat, human E430, 438, 441
- Fat, rat E430, 438, 440
- FC-47 320
- (see also 1-butanamine, 1,1,2,2,3,3,4,4,4-nonafluoro-*N,N*-bis-(nonafluorobutyl)-
- FC-80 see furan, heptafluorotetrahydro(nonafluorobutyl)-
- Formamide E304, 399
- Formamide (ternary) E384, 399
- Formamide, *N,N*-dimethyl- E303, E304, E306, E307, 342-347
- Formamide, *N,N*-dimethyl- (ternary) 348, E384, E385, 392, 406, 410, 413, 414
- Formic acid, pentyl ester E180, E187, 224
- N*-Formyl morpholine see 4-morpholinecarboxaldehyde
- Furan, heptafluorotetrahydro(nonafluorobutyl)- E256, E259, 286-288
- 2-Furanmethanol, tetrahydro- E384, 391
- Furan, tetrahydro- E181, E187, 237, 238
- Furenone, dihydro-2(3*H*)- E184, 254
- Glycerol see 1,2,3-propanetriol
- Heptadecane E6, 51
- Heptane E2, E13, 20, 27-32
- Heptane, hexadecafluoro- E256, E259, E260, 283, 284
- 1-Heptanol E132, 163, 164
- 3-Heptanone E178, 197
- 4-Heptanone E178, 196
- Herring oil E430, 432
- Hexadecane E1, E6, E13, 30, 51-56
- Hexametapol see phosphoric triamide, hexamethyl-
- Hexamethyl phosphoric triamide see phosphoric triamide, hexamethyl-
- Hexane E2, E4, E7, E9, E13, 20-27

Hexanedinitrile	E306, 354
Hexane, 1,1,1,2,2,3,3,4,4,5,5,6,6-tridecafluoro-6-[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy]-	E257, E259, E260, 289, 290
1-Hexanol	E132, 161
2-Hexanone	E178, 196
3-Hexanone	E178, 197
Hexatriacontane	E6, E7, E9, E13, 56, 60
Hydrocarbon fuel	E417, E418, 424
Hydrocyanic acid	E304, 352
Isobutyl acetate	see acetic acid, 2-methylpropyl ester
Isopropylbenzene	see benzene, (1-methylethyl)-
Kerosene	E407, E408, 419, 421, 423, 427
L-1822	E256, 285
Lard	E431, 447
Lard, steam rendered	E431, 446
Lecithin (ternary)	E385, 403
d-Limonene	see cyclohexene, 1-methyl-4-(1-methylethenyl)-
Lithium bromide (ternary)	E385, 415, 416
Lithium chloride (ternary)	E385, 415, 416
Lithium iodide (ternary)	E385, 415, 416
Linseed oil	E430, 432, 442, 443
Medicinal Oil	E418, 422
Methane	E1, E5, 14, 15, 461
Methane (ternary)	E4, 36, 37
Methane, dichloro-	E255, E259, 269, 270
Methane, dichlorodifluoro-	E255, E259, 271
Methane, sulfinylbis-	E359, E361, E362, 382, 383
Methane, tetrachloro-	E255, E259, E260, 261-264, 397
Methane, tetrachloro- (ternary)	E384, 397, 398
Methane, trichloro-	E255, E259, E260, 265-268, 401
Methane, trichloro- (ternary)	E385, 401
Methane, trichlorofluoro-	E255, E259, 271, 272
Methanol	86, 109, E128, E131, E135, 136-146, 401
Methanol (ternary)	E384-E386, 387, 388, 391, 401, 415
Methoxytriethylene glycol acetate	see acetic acid, 2-[2-(2-methoxyethoxy)ethoxy]ethanol ester
N-Methyl-ε-caprolactam	see 2H-azepin-2-one, hexahydro-1-methyl-
1,1'-Methylbis(methylbenzene)	see benzene, 1,1-methylenebis(methyl-
Methyl oleate	see 9-octadecenoic acid, methyl ester
3-Methyl-1H-pyrazole	see 1H-pyrazole, 3-methyl-
Mineral oil	E418, 422, 426
4-Morpholinecarboxaldehyde	E302, E306, 321, 322
Naphthalene, decahydro-	E8, E10, 71, 81
Naphthalene, decahydro-, cis-	E8, 82
Naphthalene, decahydro-, trans-	E8, 82
Naphthalene, 1-methyl-	E92, E94, E95, 126, 127
Naphthalene, 1,2,3,4-tetrahydro-	E10, E13, 71, 86-88
Nitrogen	E457, 460
Nitrogen oxide	E457, 462
Nonane	E5, 27, 39
1-Nonanol	E132, 166
2-Nonanone	E178, 197
3-Nonanone	E178, 197
5-Nonanone	196
Nylon 11	see poly[1-oxo-1,11-undecanediyl]]

- Octacosane E6, E9, E13, 56, 59, 60
 Octadecanoic acid (ternary) E385, 412, 414
 Octadecanoic acid, ethyl ester E181, E187, 232
 9-Octadecenoic acid (Z) E180, E187, 222
 9-Octadecenoic acid, butyl ester E181, E187, 233
 9-Octadecenoic acid, ethyl ester E181, E187, 233
 9-Octadecenoic acid, methyl ester E181, E187, 233
 Octamethylcyclotetrasiloxane
 see cyclotetrasiloxane, octamethyl-
 Octane E2, E5, E8, E13, 20, 27, 33-35
 Octane (ternary) E4, 36, 37
 1-Octanol E132, E135, 163-165, 398
 1-Octanol (ternary) E384, 398
 2-Octanone E178, 197
 3-Octanone E178, 197
 Oil E417, E418, 423-425
 see also kerosene, mineral oil, olive oil, cod liver oil,
 herring oil, linseed oil, soybean oil and cotton seed oil
 Oleic acid
 see 9-octadecenoic acid (Z)
 Olive oil E430, 432-437
 Oxygen E457, 459, 460

 Paraffin wax E418, 429
 Paraffinic oil E417, E418, 419
 Pentadecane E5, 50
 Pentane E1, E5, E7, E13, 17, 18
 Pentane, 1-bromo- E256, E259, 277
 Pentane, 1-chloro- E256, E259, E260, 278
 Pentane, 2,2,4-trimethyl- E5, E13, 38
 1-Pentanol E131, E135, 160-162
 2-Pentanone E178, 196
 3-Pentanone E178, 196
 2,5,8,11,14-Pentaoxapentadecane E182, E183, 216, 248, 249
 Perfluorobutylperfluorotetrahydrofuran
 see furan, heptafluorotetrahydro(nonafluorobutyl)-
 Perfluoro-1,4-diisopropoxylbutane
 see butane, 1,1,2,2,3,3,4,4,-octafluoro-1,4-
 bis(1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy)-
 Perfluoro-1-isopropoxyhexane
 see hexane, 1,1,1,2,2,3,3,4,4,5,5,6,6-tri
 decafluoro-6-[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethoxy]-
 Perfluoroheptane
 see heptane, hexadecafluoro-
 Perfluorotributylamine
 see 1-butanamine, 1,1,2,2,3,3,4,4,4-nonafluoro-
 N,N-bis(nonafluorobutyl)-
 Petroleum E417, E418, 421, 423, 424, 428
 Phenol E182, E184, E187, 251
 Phenol, 3-methyl- E182, E184, E187, 252
 Phenol, 3-methoxy-4-(2-propenyl)- E184, 253
 Phosphoric acid, tributyl ester 216, E358, E361, E362,
 366-370
 Phosphoric acid, triethyl ester E358, E362, 363, 370
 Phosphoric acid, trimethyl ester E358, 370
 Phosphoric acid, tripropyl ester E358, 370
 Phosphoric acid, tris(2-methylpropyl) ester E358, 370
 Phosphoric triamide, hexamethyl- 86, E358, E361, E362,
 363-365
 Polyacrylonitrile
 see 2-propenenitrile homopolymer
 Polybutadiene, hydrogenated E448, 452
 Polyethene
 see ethene homopolymer
 Poly(ethylene glycol)
 see poly(oxy-1,2-ethanediyl), α -hydro- ω -hydroxy-
 Poly(ethylene glycol) diacetate
 see poly(oxy-1,2-ethanediyl),
 α -acetyl- ω -(acetyloxy)-

- Poly(ethylene glycol) diethyl ether
see poly(oxy-1,2-ethanediyl),
α-ethyl-ω-ethoxy-
- Poly(ethylene glycol) dipropyl ether
see poly(oxy-1,2-ethanediyl),
α-propyl-ω-propoxy-
- Poly(ethylene glycol) methyl isopropyl ether
see poly(oxy-1,2-ethanediyl),
α-methyl-ω-(1-methylethoxy)-
- Poly(ethylene glycol) methyl propyl ether
see poly(oxy-1,2-ethanediyl),
α-methyl-ω-propoxy-
- Poly(ethylene terephthalate)
see poly(oxy-1,2-ethanediyl)oxycarbonyl-1,4-
phenylenecarbonyl)
- Poly[imino(1-oxo-1,11-undecanediyl)] E448, 456
- Polyisobutylene
see 1-propene, 2-methyl- homopolymer
- Poly(oxy-1,2-ethanediyl), α-acetyl-ω-(acetyloxy)-
E182, E183, 244, 245
- Poly(oxy-1,2-ethanediyl), α-ethyl-ω-ethoxy- E182, E183,
244, 245
- Poly(oxy-1,2-ethanediyl), α-hydro-ω-hydroxy- E182, E183,
244, 245
- Poly(oxy-1,2-ethanediyl), α-methyl-ω-(1-methylethoxy)-
E182, E183, 250
- Poly(oxy-1,2-ethanediyl), α-methyl-ω-propoxy- E182, E183,
244, 245
- Poly(oxy-1,2-ethanediyl), α-propyl-ω-propoxy- E182, E183,
244, 245
- Poly(oxy-1,2-ethanediyl)oxycarbonyl-1,4-phenylenecarbonyl)
E448, 450-453
- Polystyrene
see benzene, ethenyl- homopolymer
- Polyvinyl acetate
see acetic acid, ethenyl ester homopolymer
- Propane E1, E13, 14-16
- Propane, 1-bromo-2-chloro- E256, 282
- Propane, 2-bromo-1-chloro- E256, 282
- Propane, 1-chloro-2-methyl- E256, E259, 279
- Propane, 1,2-dibromo- E256, E259, 280
- 1,3-Propanediol (ternary) E384, 390
- Propane, 2,2-dimethyl- E2, E5, E13, 19
- Propane, 2-methyl- E1, E13, 16
- Propanenitrile E306, 353
- Propanenitrile, 3-(dimethylamino)- E306, 356
- 1,2,3-Propanetriol E133, 177
- 1,2,3-Propanetriol, triacetate E181, E187, 234, 235
- Propanoic acid E179, E180, E187, 221
- 1-Propanol E130, E135, 148, 153-156
- 1-Propanol (ternary) 153, E384, 400
- 2-Propanol E130, E135, 146, 149, 155, E257, E259
- 1-Propanol, 2,3-dichloro- E259
- 2-Propanol, 1,3-dichloro- E257, E259, 294
- 1-Propanol, 2-methyl- E131, E135, 149, 158, 159
399, 405
- 1-Propanol, 2-methyl- (ternary) E384, E385, 399, 405
- Propanol, oxybis- E181, E187, 241
- Propanol, oxybis- (ternary) E384, 390
- 2-Propanone E178, E179, E187, E188, 189-198, 401
- 2-Propanone (ternary) E385, 199, 401, 407, 411, 412
- Propene E8, E10, 14, 15, 83, 84
- 1-Propene, 2-methyl- homopolymer (ternary) E385, 409
- 2-Propenenitrile homopolymer (ternary) E385, 410
- Propylene bromide
see propane, 1,2-dibromo-
- Propylene carbonate
see 1,3-dioxolan-2-one, 4-methyl-
- Propylene glycol
see 1,3-propanediol

1 <i>H</i> -Pyrazole, 1,3-dimethyl-	E303, E306, 324
1 <i>H</i> -Pyrazole, 1-ethyl-3-methyl-	E303, E306, 325
1 <i>H</i> -Pyrazole, 3-methyl-	E303, E306, 323
1 <i>H</i> -Pyrazole, methyl(3-methylbutyl)-	E303, E306, 327
1 <i>H</i> -Pyrazole, methyl(1-methylethyl)-	E303, E306, 326
Pyridine	E302, E306, E307, 309, 315, 316
2-Pyrrolidinone (ternary)	E384, 393
2-Pyrrolidinone, 1-methyl-	86, 216, E303, E306, E307, 329-341
2-Pyrrolidinone, 1-methyl- (ternary)	E384, 392-396
Quinoline	E302, E306, E307, 317, 318
<i>Ramol</i> 351	E418, 425
Rubber	E448, 454
Rubber, natural	E448, 449
<i>Sepasolv</i> MPE	E182, E183, 250
Silane, tetramethyl-	E359, 372
Sodium iodide (ternary)	E385, 411, 413, 415, 416
Soybean oil	E430, 444, 445
Squalane	
Stearic acid	see tetracosane, 2,6,10,15,19,23-hexamethyl-
	see octadecanoic acid
Sulfinylbismethane	see methane, sulfinylbis-
Sulfolane	see thiophene, tetrahydro-, 1,1-dioxide
Tetracosane, 2,6,10,15,19,23-hexamethyl-	E7, E9, E13, 57
Tetradecane	E6, E10, E13, 48, 49
1-Tetradecene	E10, E13, 71
Tetraethylene glycol	
	see ethanol, 2,2'-[oxylbis(2,1-ethanedioxy)]bis-
Tetraethylene glycol dimethyl ether	
	see 2,5,8,11,14-pentaoxapentadecane
Tetrahydrofurfuryl alcohol	
	see 2-furanmethanol, tetrahydro-
Tetrahydrothiophene, 1,1-dioxide	
	see thiophene, tetrahydro-, 1,1-dioxide
Tetralin	
	see naphthalene, 1,2,3,4-tetrahydro-
Tetramethylsilane	
	see silane, tetramethyl-
2,5,8,11-Tetraoxadodecane	E182, E183, 249
3,6,9,12-Tetraoxatetradecane	E182, E183, 244, 245
Tetratetracontane	E7, E13, 60
Thiophene, tetrahydro-, 1,1-dioxide	E359, E361, E362, 373-377
<i>m</i> -Toluidine	
	see benzenamine, 3-methyl-
<i>o</i> -Toluidine	
	see benzenamine, 2-methyl-
Triacetin	
	see 1,2,3-propanetriol, triacetate
Tributyl phosphate	
	see phosphoric acid, tributyl ester
Tridecane	E5, 47
Triethylene glycol	
	see ethanol, 2,2'-[1,2-ethanediylbis(oxy)]bis-
Triethylene glycol butyl ether	
	see 3,6,9-trioxatridecan-1-ol
Triethylene glycol diethyl ether	
	see 3,6,9,12-tetraoxatetradecane
Triethyl phosphate	
	see phosphoric acid, triethyl ester
Triisobutyl phosphate	
	see phosphoric acid, tris(2-methylpropyl) ester

Trimethyl phosphate	
see phosphoric acid, trimethyl ester	
3,6,9-Trioxatridecan-1-ol	E182, E183, 249
Tripropyl phosphate	
see phosphoric acid, tripropyl ester	
Undecane	E5, 27, 44
1-Undecanol	E132, 168
2-Undecanone	E178, 197
Water	86, 174
Water (ternary)	174
Wax	E418, 429

REGISTRY NUMBER INDEX

Page numbers preceded by E refer to evaluation texts whereas page numbers not preceded by E refer to compiled tables.

56-23-5	E255, E259, E260, 261-264, E384, 397, 398
56-81-5	E133, 177
57-11-4	E385, 412, 414
57-88-5	E385, 404, 405
60-29-7	E181-E183, E187, 236
62-53-3	E302, E306, E307, 308-312
64-17-5	E128, E131, E135, 137, 138, 146-148, 150-153, E183, E384, E386, 416
64-19-7	E179, E180, E187, E188, 218, 219
67-56-1	86, 109, E128, E131, E135, 136-146, E384-E386, 387, 388, 391, 402, 415
67-63-0	E130, E135, 146, 149, 155, E257, E259
67-64-1	E178, E179, E187, E188, 198, 189-196, E385, 402, 407, 411, 412
67-66-3	E255, E259, E260, 265-268, E385, 402
67-68-5	E359, E361, E362, 382, 383
68-12-2	E303, E304, E306, E307, 342-348, E384, E385, 392, 406, 410, 413, 414
71-23-8	E130, E135, 148, 153-156, E384, 400
71-36-3	E130, E135, 146, 149, 157
71-41-0	E131, E135, 160-162
71-43-2	E90, E94, E95, 96-98, 100-105, 114, E257, E384, E385, 397, 400-404, 408, 409
74-82-8	E1, E4, E5, 14, 15, 36, 37, 461
74-84-0	E1, E8, 14-16, 85
74-85-1	E8, E10, 83, 85
74-86-2	E178, 199, E303, E304, 348
74-90-8	E304, 352
74-98-6	E1, E13, 14-16
75-07-0	E178, E179, 204
75-09-2	E255, E259, 269, 270
75-12-7	E304, E384, 399

SOLUBILITY DATA SERIES

- Volume 1 H. L. Clever, *Helium and Neon*
- Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
- Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
- Volume 4 H. L. Clever, *Argon*
- Volume 5/6 C. L. Young, *Hydrogen and Deuterium*
- Volume 7 R. Battino, *Oxygen and Ozone*
- Volume 8 C. L. Young, *Oxides of Nitrogen*
- Volume 9 W. Hayduk, *Ethane*
- Volume 10 R. Battino, *Nitrogen and Air*
- Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline Earth Metal and Ammonium Halides, Amide Solvents*
- Volume 12 C. L. Young, *Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides*
- Volume 13 S. Siekierski, T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Nitrates*
- Volume 14 H. Miyamoto, M. Salomon and H. L. Clever, *Alkaline Earth Metal Halates*
- Volume 15 A. F. M. Barton, *Alcohols with Water*
- Volume 16/17 E. Tomlinson and A. Regosz, *Antibiotics: 1, β -Lactam Antibiotics*
- Volume 18 O. Popovych, *Tetraphenylborates*
- Volume 19 C. L. Young, *Cumulative Index: Volumes 1-18*
- Volume 20 A. L. Horvath and F. W. Getzen, *Halogenated Benzenes, Toluenes and Phenols with Water*
- Volume 21 C. L. Young and P. G. T. Fogg, *Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents*
- Volume 22 T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents*
- Volume 23 T. P. Dirkse, *Copper, Silver, Gold and Zinc, Cadmium, Mercury Oxides and Hydroxides*
- Volume 24 W. Hayduk, *Propane, Butane and 2-Methylpropane*
- Volume 25 C. Hirayama, Z. Galus and C. Guminski, *Metals in Mercury*
- Volume 26 M. R. Masson, H. D. Lutz and B. Engelen, *Sulfites, Selenites and Tellurites*
- Volume 27/28 H. L. Clever and C. L. Young, *Methane*
- Volume 29 H. L. Clever, *Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements*
- Volume 30 H. Miyamoto and M. Salomon, *Alkali Metal Halates, Ammonium Iodate and Iodic Acid*
- Volume 31 J. Eysseľtová and T. P. Dirkse, *Alkali Metal Orthophosphates*

- Volume 32 P. G. T. Fogg and C. L. Young, *Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide*
- Volume 33 P. Franzosini, *Molten Alkali Metal Alkanoates*
- Volume 34 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides*.
Part I: Non-cyclic Substituents
- Volume 35 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides*.
Part II: 5-Membered Heterocyclic Substituents
- Volume 36 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides*.
Part III: 6-Membered Heterocyclic Substituents and Miscellaneous Systems
- Volume 37 D. G. Shaw, *Hydrocarbons with Water and Seawater*.
Part I: Hydrocarbons C₅ to C₇
- Volume 38 D. G. Shaw, *Hydrocarbons with Water and Seawater*.
Part II: Hydrocarbons C₈ to C₃₆
- Volume 39 C. L. Young, *Cumulative Index: Volumes 20-38*
- Volume 40 J. Hala, *Halides, Oxyhalides and Salts of Halogen Complexes of Titanium, Zirconium, Hafnium, Vanadium, Niobium and Tantalum*
- Volume 41 C.-Y. Chan, I. N. Lepeshkov and K. H. Khoo, *Alkaline Earth Metal Perchlorates*
- Volume 42 P. G. T. Fogg and W. Gerrard, *Hydrogen Halides in Non-aqueous Solvents*
- Volume 43 R. W. Cargill, *Carbon Monoxide*
- Volume 44 H. Miyamoto, E. M. Woolley and M. Salomon, *Copper and Silver Halates*
- Volume 45/46 R. P. T. Tomkins and N. P. Bansal, *Gases in Molten Salts*
- Volume 47 R. Cohen-Adad and J. W. Lorimer, *Alkali Metal and Ammonium Chlorides in Water and Heavy Water (Binary Systems)*
- Volume 48 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part I: Esters 2-C to 6-C*
- Volume 49 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water*.
Part II: Esters 7-C to 32-C
- Volume 50 P. G. T. Fogg, *Carbon Dioxide in Non-aqueous Solvents at Pressures less than 200 kPa*
- Volume 51 J. G. Osteryoung, M. M. Schreiner, C. Guminski and Z. Galus, *Intermetallic Compounds in Mercury*
- Volume 52 I. Lambert and H. L. Clever, *Alkaline Earth Hydroxides in Water and Aqueous Solutions*
