FOREWORD

*If the knowledge is
undigested or simply wrong,
more is not better*

The Solubility Data Series is a project of Commission V.8 (Solubility Data) of the International Union of Pure and Applied Chemistry (IUPAC). The project had its origins in 1973, when the Analytical Chemistry Division of IUPAC set up a Subcommission on Solubility Data under the chairmanship of the late Prof. A. S. Kertes. When publication of the *Solubility Data Series* began in 1979, the Committee became a full commission of IUPAC, again under the chairmanship of Prof. Kertes, who also became Editor-in-Chief of the Series. The Series has as its goal the preparation of a comprehensive and critical compilation of data on solubilities in all physical systems, including gases, liquids and solids.

The motivation for the Series arose from the realization that, while solubility data are of importance in a wide range of fields in science and technology, the existing data had not been summarized in a form that was at the same time comprehensive and complete. Existing compilations of solubility data indeed existed, but they contained many errors, were in general uncritical, and were seriously out-of-date.

It was also realized that a new series of compilations of data gave educational opportunities, in that careful compilations of existing data could be used to demonstrate what constitutes data of high and lasting quality. As well, if the data were summarized in a sufficiently complete form, any individual could prepare his or her own evaluation, independently of the published evaluation. Thus, a special format was established for each volume, consisting of individual data sheets for each separate publication, and critical evaluations for each separate system, provided sufficient data from different sources were available for comparison. The compilations and, especially, the evaluation were to be prepared by active scientists who were either involved in producing new data, or were interested in using data of high quality. With minor modifications in format, this strategy has continued throughout the Series.

In the standard arrangement of each volume, the Critical Evaluation gives the following information

(i) A text which discusses the numerical solubility information which has been abstracted from the primary sources in the form of compilation sheets. The text concerns primarily the quality of the data, after consideration of the purity of the materials and their characterization, the experimental method used, the uncertainties in the experimental values, the reproducibility, the agreement with accepted test values, and finally, the fitting of the data to suitable functions, along with statistical tests of the fitted data.

(ii) A set of recommended data, whenever possible, including weighted averages and estimated standard deviations. If applicable, one or more smoothing equations which have been computed or verified by the evaluator are also given.

(iii) A graphical plot of the recommended data, in the form of phase diagrams where appropriate

The Compilation part consists of data sheets which summarize the experimental data from the primary literature. Here much effort is put into obtaining complete coverage, many good data have appeared in publications from the late nineteenth and early twentieth centuries, or in obscure journals. Data of demonstrably low precision are not compiled, but are mentioned in the Critical Evaluation. Similarly, graphical data, given the uncertainty of accurate conversion to numerical values, are compiled only where no better data are available. The documentation of data of low precision can serve to alert researchers to areas where more work is needed.

A typical data sheet contains the following information:

- (i) list of components: names, formulas, Chemical Abstracts Registry Numbers;
- (ii) primary source of the data;
- (iii) experimental variables;
- (iv) compiler's name;
- (v) experimental values as they appear in the primary source, in modern units with explanations if appropriate;
- (vi) experimental methods used;
- (vii) apparatus and procedure used;
- (viii) source and purity of materials used;
- (ix) estimated error, either from the primary source or estimated by the compiler;
- (x) references relevant to the generation of the data cited in the primary source.

Each volume also contains a general introduction to the particular type of system, such as solubility of gases, of solids in liquids, etc., which contains a discussion of the nomenclature used, the principle of accurate determination of solubilities, and related thermodynamic principles. This general introduction is followed by a specific introduction to the subject matter of the volume itself.

The Series embodies a new approach to the presentation of numerical data, and the details continue to be influenced strongly by the perceived needs of prospective users. The approach used will, it is hoped, encourage attention to the quality of new published work, as authors become more aware that their work will attain permanence only if it meets the standards set out in these volumes. If the Series succeeds in this respect, even partially, the Solubility Data Commission will have justified the labour expended by many scientists throughout the world in its production.

PREFACE

This volume presents solubility data for the hydroxides of the alkaline earth metals Be, Mg, Ca, Sr and Ba in water and aqueous solutions. No data were found for radium hydroxide. The literature has been covered up to 1990. The primary literature sources were *Chemical Abstracts*, and the reference books by Seidell and Linke (1), Gmelin (2), Pascal (3) and Mellor (4).

The calcium, strontium and barium hydroxides were used in sugar refining in the last century. Thus, it is not surprising that the first publications of solubility data for these hydroxides are to be found in the older literature connected with this industrial process. However, few quantitative data are available from these older publications and only published reports of quantitative data have been compiled. Many of these older papers are cited at the end of the evaluation reference lists. A partial listing of papers that report solubility studies of alkaline earth hydroxide containing systems, but contain no data on the alkaline earth hydroxide component, have also been appended to the evaluation reference lists.

The alkaline earth metal hydroxides can be divided into two groups depending on the hydration of the solid. One group consists of the sparingly soluble anhydrous hydroxides of beryllium, magnesium and calcium. The solubility of the magnesium and calcium hydroxides decreases with increasing temperature. Beryllium hydroxide probably has the same temperature coefficient of solubility, but the experimental solubility data are ambiguous. The more soluble strontium and barium hydroxides are octahydrates at room temperature and above. Their solubility increases with increasing temperature.

The alkaline earth hydroxides are strong bases which ionize in aqueous solution according to the solubility equilibrium

The solubility depends strongly on pH. The thermodynamic solubility product is

$$K_{so}^0 = a(M^{2+})a(OH^-)^2a(H_2O)^r \quad [1]$$

Because formation of ion pairs (and of higher complexes in the case of beryllium hydroxide) is important in solutions of these hydroxides, expressing the solubility product in pure water in terms of the molality, m , of the saturated solution, the mean activity coefficient, γ_{\pm} , and the osmotic coefficient, ϕ , requires as well the degree of association, α , thus

$$K_{so}^0 = 4\gamma_{\pm}^3(1 - \alpha)^3m^3\exp(-3r(1 - \alpha)\phi) \quad [2]$$

It should be noted that the averaged evaluated solubility data alone are not of sufficient accuracy to derive values of the association constants from the fit of a model to the solubility data. The association constants must be determined by other methods such as spectrophotometry.

The solubility also depends on the crystalline state of the hydroxide. The freshly precipitated hydroxide is generally a poorly crystallized product. On aging the crystallinity improves and the substance is less soluble. This is especially true of the beryllium, magnesium and calcium hydroxides which form non-hydrated solids. The solid strontium and barium hydroxides which are hydrated do not show differences in solubility with aging.

The alkaline earth metal cations form salts with a wide range of solubilities with two common anions, the hydroxide and the sulfate. The accompanying figure shows solubilities at 298 K of the stable solid phase of these two series of substances as a function of cation atomic number. It is clear that the solubilities of the solid increase with increasing cation atomic number, while those of the sulfates decrease. Quantitative discussion of these differences must take account of the complications arising from the occurrence of hydrates $BeSO_4 \cdot 4H_2O$, $MgSO_4 \cdot 6H_2O$, $CaSO_4 \cdot 2H_2O$, $Sr(OH)_2 \cdot 8H_2O$ and $Ba(OH)_2 \cdot 8H_2O$, as well as the variety of crystal structures for the various solid phases. However, the general trends are clear when the Gibbs energy and enthalpy for the solubility

equilibria are considered as the resultant of decomposition of the crystal lattice plus hydration and complexation of the separated ions.

The solubility of the alkaline earth hydroxides and sulfates as a function of cation atomic number, 298 K.

First of all, the decrease of solubility with temperature of $\text{Mg}(\text{OH})_2$ and $\text{Ca}(\text{OH})_2$ indicates that the magnitude of the enthalpy of solvation is greater than the magnitude of the lattice enthalpy. For the octahydrates, the ions are already largely solvated in the crystal lattice, so the lattice enthalpy predominates. For the sulfates, the solubility generally increases with increasing temperature (except for a reversal of sign for SrSO_4 above room temperature), indicating the predominance of the lattice enthalpy in determining solubility.

Secondly, the magnitude of the thermodynamic solubility product is determined by the Gibbs energy, which can be split into contributions from entropy and enthalpy of lattice decomposition and solvation. We can postulate that the entropy of solvation is much larger for the hydroxide ion than for the sulfate ion: the hydroxide tends to lose its identity when solvated. Thus the entropy and enthalpy terms are determined mainly by the hydroxide ions, and have roughly the same magnitude for the Be, Mg and Ca hydroxides, so that the solubilities are low. For the Sr and Ba hydroxide octahydrates the hydroxide ions are already hydrated in the crystal, so the solubilities are greater, and not too different. For the sulfates, solvation is restricted to the cations, and decreases with decreasing charge density, i.e. as the atomic number increases. Thus, with increasing atomic number, the enthalpy and entropy contributions to the Gibbs energy become smaller and more equal, and the solubility decreases.

These general conclusions are supported by those thermodynamic values for standard state solvation enthalpies which can be calculated from tabulated data (6). More precise conclusions depend on knowledge of the detailed structure of the crystalline phases and of the saturated solutions.

General procedures for Evaluation

(a) Beryllium hydroxide. No reliable data for the temperature coefficient of solubility are available. The critical evaluation makes use of ancillary data relating to the structure and composition of dilute solutions of beryllium hydroxide.

(b) Other hydroxides. General equations for the activity coefficients under all conditions of temperature and composition were examined, but the number of unknown, but necessary parameters, was sufficiently large that a simpler approach was adopted for fitting the solubility data as a function of temperature. Under the assumptions that the factors containing activity and osmotic coefficients and the degree of associa-

tion in eqn [1] follow the same temperature dependence along the solubility curve as does the solubility itself, and that the enthalpy of solution can be expressed by a general equation which is discussed in the *Introduction to the Series on Solubility of Solids in Liquids* in this volume, two fitting equations were used. For anhydrous solid phases in contact with pure water,

$$Y_m = \ln(m/m^0) = B_1 + B_2K/T + B_3\ln(T/K) \quad [3]$$

where m is the molality, m^0 the standard molality of 1 mol kg⁻¹, T the thermodynamic temperature, and B_i , $i = 1, 2, 3$ are constants found by least square fits to the experimental data.

For the hydrated solid phases,

$$Y_m = \ln(m/m^*) - (m/m^* - 1) = A_1 + A_2K/T + A_3\ln(T/K) \quad [4]$$

where $m^* = 1/rM_w$ is the molality at the metastable congruent melting point of the salt hydrate, with M_w the molar mass of water, and A_i , $i = 1, 2, 3$ constants, again found by a least square fit to the experimental data. Once the coefficients of this equation are found, an estimation of the congruent melting point can be made by setting $Y_m = 0$. When this equation has been applied to data with a known saturating solid phase over a particular range of temperature, then data at higher temperatures can be tested for consistency with the given solid phase.

For ternary and higher systems, and for non-aqueous systems, sufficient data for reliable evaluation are rarely available. Those data that do exist are summarized in the critical evaluations.

The editors gratefully acknowledge the advice and comments from members of the IUPAC Commission V.8 on Solubility Data, in particular Dr. Mark Salomon, Chairman, IUPAC Commission V.8, and Professor J. W. Lorimer, Editor-in-Chief, for their constructive criticisms and suggestions. Professor Lorimer suggested and contributed to the comparison of the hydroxide and sulfate solubilities above. We also thank Ms. Marian Iwamoto for her help in typing parts of the manuscript.

INTRODUCTION TO THE SOLUBILITY OF SOLIDS IN LIQUIDS

Nature of the Project

The Solubility Data Project (SDP) has as its aim a comprehensive search of the literature for solubilities of gases, liquids, and solids in liquids or solids. Data of suitable precision are compiled on data sheets in a uniform format. The data for each system are evaluated, and where data from different sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

Definitions

A mixture (1, 2) describes a gaseous, liquid, or solid phase containing more than one substance, when the substances are all treated in the same way.

A solution (1, 2) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the solvent, and may itself be a mixture, is treated differently than the other substances, which are called solutes. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a dilute solution.

The solubility of a substance B is the relative proportion of B (or a substance related chemically to B) in a mixture which is saturated with respect to solid B at a specified temperature and pressure. Saturated implies the existence of equilibrium with respect to the processes of dissolution and precipitation; the equilibrium may be stable or metastable. The solubility of a substance in metastable equilibrium is usually greater than that of the corresponding substance in stable equilibrium. (Strictly speaking, it is the activity of the substance in metastable equilibrium that is greater.) Care must be taken to distinguish true metastability from supersaturation, where equilibrium does not exist.

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the quantities used as measures of solubility and in the reference states used for definition of activities, activity coefficients and osmotic coefficients.

The qualifying phrase "substance related chemically to B" requires comment. The composition of the saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components. Thus, the solubility of a salt hydrate in water is usually given as the relative proportion of anhydrous salt in solution, rather than the relative proportions of hydrated salt and water.

Quantities Used as Measures of Solubility

1. Mole fraction of substance B, x_B :

$$x_B = n_B / \sum_{s=1}^c n_s \quad [1]$$

where n_s is the amount of substance of s , and c is the number of distinct substances present (often the number of thermodynamic components in the system). Mole per cent of B is 100 x_B .

2. Mass fraction of substance B, w_B :

$$w_B = m_B' / \sum_{s=1}^c m_s' \quad [2]$$

where m_s' is the mass of substance s . Mass per cent is 100 w_B . The equivalent terms weight fraction and weight per cent are not used.

3. Solute mole (mass) fraction of solute B (3, 4):

$$x_{s,B} = m_B / \sum_{s=1}^{c'} m_s = x_B / \sum_{s=1}^{c'} x_s \quad [3]$$

$$w_{s,B} = m_B' / \sum_{s=1}^{c'} m_s' = w_B / \sum_{s=1}^{c'} w_s \quad [3a]$$

where the summation is over the solutes only. For the solvent A, $x_{S,A} = x_A/(1 - x_A)$, $w_{S,A} = w_A/(1 - w_A)$. These quantities are called Jänecke mole (mass) fractions in many papers.

4. Molality of solute B (1, 2) in a solvent A:

$$m_B = n_B/n_A M_A \quad \text{SI base units: mol kg}^{-1} \quad [4]$$

where M_A is the molar mass of the solvent.

5. Concentration of solute B (1, 2) in a solution of volume V:

$$c_B = [B] = n_B/V \quad \text{SI base units: mol m}^{-3} \quad [5]$$

The symbol c_B is preferred to $[B]$, but both are used. The terms molarity and molar are not used.

Mole and mass fractions are appropriate to either the mixture or the solution point of view. The other quantities are appropriate to the solution point of view only. Conversions among these quantities can be carried out using the equations given in Table 1-1 following this Introduction. Other useful quantities will be defined in the prefaces to individual volumes or on specific data sheets.

In addition to the quantities defined above, the following are useful in conversions between concentrations and other quantities.

6. Density: $\rho = m/V$ SI base units: kg m^{-3} [6]

7. Relative density: d ; the ratio of the density of a mixture to the density of a reference substance under conditions which must be specified for both (1). The symbol d_t will be used for the density of a mixture at $t^\circ\text{C}$, 1 bar divided by the density of water at $t^\circ\text{C}$, 1 bar. (In some cases 1 atm = 101.325 kPa is used instead of 1 bar = 100 kPa.)

8. A note on nomenclature. The above definitions use the nomenclature of the IUPAC Green Book (1), in which a solute is called B and a solvent A. In compilations and evaluations, the first-named component (component 1) is the solute, and the second (component 2 for a two-component system) is the solvent. The reader should bear these distinctions in nomenclature in mind when comparing nomenclature and theoretical equations given in this Introduction with equations and nomenclature used on the evaluation and compilation sheets.

Thermodynamics of Solubility

The principal aims of the Solubility Data Project are the tabulation and evaluation of: (a) solubilities as defined above; (b) the nature of the saturating phase. Thermodynamic analysis of solubility phenomena has two aims: (a) to provide a rational basis for the construction of functions to represent solubility data; (b) to enable thermodynamic quantities to be extracted from solubility data. Both these are difficult to achieve in many cases because of a lack of experimental or theoretical information concerning activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve critical evaluation of a large body of data that is not directly relevant to solubility. The following is an outline of the principal thermodynamic relations encountered in discussions of solubility. For more extensive discussions and references, see books on thermodynamics, e.g., (5-12).

Activity Coefficients (1)

(a) Mixtures. The activity coefficient f_B of a substance B is given by

$$RT \ln (f_B x_B) = \mu_B - \mu_B^* \quad [7]$$

where μ_B^* is the chemical potential of pure B at the same temperature and pressure. For any substance B in the mixture,

$$\lim_{x_B \rightarrow 1} f_B = 1 \quad [8]$$

(b) Solutions.

(1) Solute B. The molal activity coefficient γ_B is given by

$$RT \ln (\gamma_B m_B) = \mu_B - (\mu_B - RT \ln m_B)^\infty \quad [9]$$

where the superscript $^\infty$ indicates an infinitely dilute solution. For any solute B,

$$\gamma_B^\infty = 1 \quad [10]$$

Activity coefficients γ_B connected with concentrations c_B , and $f_{x,B}$ (called the rational activity coefficient) connected with mole fractions x_B are defined in analogous ways. The relations among them are (1, 9), where ρ^* is the density of the pure solvent:

$$f_B = (1 + M_A \sum_S m_S) \gamma_B = [\rho + \sum_S (M_A - M_S) c_S] \gamma_B / \rho^* \quad [11]$$

$$\gamma_B = (1 - \sum_S x_S) f_{x,B} = (\rho - \sum_S M_S c_S) \gamma_B / \rho^* \quad [12]$$

$$\gamma_B = \rho^* f_{x,B} [1 + \sum_S (M_S / M_A - 1) x_S] / \rho = \rho^* (1 + \sum_S M_S m_S) \gamma_B / \rho \quad [13]$$

For an electrolyte solute $B = C_{\nu+} A_{\nu-}$, the activity on the molality scale is replaced by (9)

$$\gamma_{BmB} = \gamma_{\pm}^{\nu} m_B^{\nu} Q^{\nu} \quad [14]$$

where $\nu = \nu_+ + \nu_-$, $Q = (\nu_+^{\nu_+} \nu_-^{\nu_-})^{1/\nu}$, and γ_{\pm} is the mean ionic activity coefficient on the molality scale. A similar relation holds for the concentration activity, γ_{cB} . For the mole fractional activity,

$$f_{x,B} x_B = Q^{\nu} f_{\pm}^{\nu} x_{\pm}^{\nu} \quad [15]$$

where $x_{\pm} = (x_+ x_-)^{1/\nu}$. The quantities x_+ and x_- are the ionic mole fractions (9), which are

$$x_+ = \nu_+ x_B / [1 + \sum_S (\nu_S - 1) x_S]; \quad x_- = \nu_- x_B [1 + \sum_S (\nu_S - 1) x_S] \quad [16]$$

where ν_S is the sum of the stoichiometric coefficients for the ions in a salt with mole fraction x_S . Note that the mole fraction of solvent is now

$$x_A' = (1 - \sum_S \nu_S x_S) / [1 + \sum_S (\nu_S - 1) x_S] \quad [17]$$

so that

$$x_A' + \sum_S \nu_S x_S = 1 \quad [18]$$

The relations among the various mean ionic activity coefficients are:

$$f_{\pm} = (1 + M_A \sum_S \nu_S m_S) \gamma_{\pm} = [\rho + \sum_S (\nu_S M_A - M_S) c_S] \gamma_{\pm} / \rho^* \quad [19]$$

$$\gamma_{\pm} = \frac{(1 - \sum_S x_S) f_{\pm}}{1 + \sum_S (\nu_S - 1) x_S} = (\rho - \sum_S M_S c_S) \gamma_{\pm} / \rho^* \quad [20]$$

$$\gamma_{\pm} = \frac{\rho^* [1 + \sum_S (M_S / M_A - 1) x_S] f_{\pm}}{\rho [1 + \sum_S (\nu_S - 1) x_S]} = \rho^* (1 + \sum_S M_S m_S) \gamma_{\pm} / \rho \quad [21]$$

(11) Solvent, A:

The osmotic coefficient, ϕ , of a solvent A is defined as (1):

$$\phi = (\mu_A^* - \mu_A) / RT M_A \sum_S m_S \quad [22]$$

where μ_A^* is the chemical potential of the pure solvent.

The rational osmotic coefficient, ϕ_x , is defined as (1):

$$\phi_x = (\mu_A - \mu_A^*) / RT \ln x_A = \phi M_A \sum_S m_S / \ln(1 + M_A \sum_S m_S) \quad [23]$$

The activity, a_A , or the activity coefficient, f_A , is sometimes used for the solvent rather than the osmotic coefficient. The activity coefficient is defined relative to pure A, just as for a mixture.

For a mixed solvent, the molar mass in the above equations is replaced by the average molar mass; i.e., for a two-component solvent with components J, K, M_A becomes

$$M_A = M_J + (M_K - M_J) x_{v,K} \quad [24]$$

where $x_{v,K}$ is the solvent mole fraction of component K.

The osmotic coefficient is related directly to the vapor pressure, p , of a solution in equilibrium with vapor containing A only by (12, p.306):

$$\phi M_A \sum_S \nu_S m_S = - \ln(p/p_A^*) + (V_{m,A}^* - B_{AA})(p - p_A^*) / RT \quad [25]$$

where p_A^* , $V_{m,A}^*$ are the vapor pressure and molar volume of pure solvent A, and B_{AA} is the second virial coefficient of the vapor.

The Liquid Phase

A general thermodynamic differential equation which gives solubility as a function of temperature, pressure and composition can be derived. The approach is similar to that of Kirkwood and Oppenheim (7); see also (11, 12). Consider a solid mixture containing c thermodynamic components 1. The Gibbs-Duhem equation for this mixture is:

$$\sum_{i=1}^c x_i' (S_i' dT - V_i' dp + d\mu_i') = 0 \quad [26]$$

A liquid mixture in equilibrium with this solid phase contains c' thermodynamic components 1, where $c' > c$. The Gibbs-Duhem equation for the liquid mixture is:

$$\sum_{i=1}^c x_i (S_i dT - V_i dp + d\mu_i') + \sum_{i=c+1}^{c'} x_i (S_i dT - V_i dp + d\mu_i) = 0 \quad [27]$$

Subtract [26] from [27] and use the equation

$$d\mu_i = (d\mu_i)_{T,p} - S_i dT + V_i dp \quad [28]$$

and the Gibbs-Duhem equation at constant temperature and pressure:

$$\sum_{i=1}^c x_i (d\mu_i')_{T,p} + \sum_{i=c+1}^{c'} x_i (d\mu_i)_{T,p} = 0 \quad [29]$$

The resulting equation is:

$$RT \sum_{i=1}^c x_i' (d \ln a_i)_{T,p} = \sum_{i=1}^c x_i' (H_i - H_i') dT/T - \sum_{i=1}^c x_i' (V_i - V_i') dp \quad [30]$$

where

$$H_i - H_i' = T(S_i - S_i') \quad [31]$$

is the enthalpy of transfer of component 1 from the solid to the liquid phase at a given temperature, pressure and composition, with H_i and S_i the partial molar enthalpy and entropy of component 1.

Use of the equations

$$H_i - H_i^0 = -RT^2 (\partial \ln a_i / \partial T)_{x,p} \quad [32]$$

and

$$V_i - V_i^0 = RT (\partial \ln a_i / \partial p)_{x,T} \quad [33]$$

where superscript 0 indicates an arbitrary reference state gives:

$$RT \sum_{i=1}^c x_i' d \ln a_i = \sum_{i=1}^c x_i' (H_i^0 - H_i') dT/T - \sum_{i=1}^c x_i' (V_i^0 - V_i') dp \quad [34]$$

where

$$d \ln a_i = (d \ln a_i)_{T,p} + (\partial \ln a_i / \partial T)_{x,p} dT + (\partial \ln a_i / \partial p)_{x,T} dp \quad [35]$$

The terms involving enthalpies and volumes in the solid phase can be written as:

$$\sum_{i=1}^c x_i' H_i' = H_S^* \quad \sum_{i=1}^c x_i' V_i' = V_S^* \quad [36]$$

With eqn [36], the final general solubility equation may then be written:

$$RT \sum_{i=1}^c x_i' d \ln a_i = (H_S^* - \sum_{i=1}^c x_i' H_i^0) d(1/T) - (V_S^* - \sum_{i=1}^c x_i' V_i^0) dp/T \quad [37]$$

Note that those components which are not present in both phases do not appear in the solubility equation. However, they do affect the solubility through their effect on the activities of the solutes.

Several applications of eqn [37] (all with pressure held constant) will be discussed below. Other cases will be discussed in individual evaluations.

(a) Solubility as a function of temperature.

Consider a binary solid compound A_mB in a single solvent A. There is

no fundamental thermodynamic distinction between a binary compound of A and B which dissociates completely or partially on melting and a solid mixture of A and B; the binary compound can be regarded as a solid mixture of constant composition. Thus, with $c = 2$, $x_A' = n/(n+1)$, $x_B' = 1/(n+1)$, eqn [37] becomes:

$$d \ln(a_A^n a_B) = -\Delta H_{AB}^0 d(1/RT) \quad [38]$$

where

$$\Delta H_{AB}^0 = nH_A + H_B - (n+1)H_S^* \quad [39]$$

is the molar enthalpy of melting and dissociation of pure solid A_nB to form A and B in their reference states. Integration between T and T_0 , the melting point of the pure binary compound A_nB , gives:

$$\ln(a_A^n a_B) = \ln(a_A^n a_B)_{T=T_0} - \int_{T_0}^T \Delta H_{AB}^0 d(1/RT) \quad [40]$$

(i) Non-electrolytes

In eqn [32], introduce the pure liquids as reference states. Then, using a simple first-order dependence of ΔH_{AB}^* on temperature, and assuming that the activity coefficients conform to those for a simple mixture (6):

$$RT \ln f_A = wx_B^2 \quad RT \ln f_B = wx_A^2 \quad [41]$$

then, if w is independent of temperature, eqn [32] and [33] give:

$$\ln\{x_B(1-x_B)^n\} + \ln\left\{\frac{n^n}{(1+n)^{n+1}}\right\} = G(T) \quad [42]$$

where

$$G(T) = - \left\{ \frac{\Delta H_{AB}^* - T^* \Delta C_p^*}{R} \right\} \left\{ \frac{1}{T} - \frac{1}{T^*} \right\} + \frac{\Delta C_p^*}{R} \ln(T/T^*) - \frac{w}{R} \left\{ \frac{x_A^2 + nx_B^2}{T} - \frac{n}{(n+1)T^*} \right\} \quad [43]$$

where ΔC_p^* is the change in molar heat capacity accompanying fusion plus decomposition of the pure compound to pure liquid A and B at temperature T^* , (assumed here to be independent of temperature and composition), and ΔH_{AB}^* is the corresponding change in enthalpy at $T = T^*$. Equation [42] has the general form:

$$\ln\{x_B(1-x_B)^n\} = A_1 + A_2/(T/K) + A_3 \ln(T/K) + A_4(x_A^2 + nx_B^2)/(T/K) \quad [44]$$

If the solid contains only component B, then $n = 0$ in eqn [42] to [44].

If the infinite dilution reference state is used, then:

$$RT \ln f_{x,B} = w(x_A^2 - 1) \quad [45]$$

and [39] becomes

$$\Delta H_{AB}^\infty = nH_A^* + H_B^\infty - (n+1)H_S^* \quad [46]$$

where ΔH_{AB}^∞ is the enthalpy of melting and dissociation of solid compound A_nB to the infinitely dilute reference state of solute B in solvent A; H_A^* and H_B^∞ are the partial molar enthalpies of the solute and solvent at infinite dilution. Clearly, the integral of eqn [32] will have the same form as eqn [35], with ΔH_{AB}^∞ replacing ΔH_{AB}^* , ΔC_p^∞ replacing ΔC_p^* , and $x_A^2 - 1$ replacing x_A^2 in the last term.

See (5) and (11) for applications of these equations to experimental data.

(ii) Electrolytes

(a) Mole fraction scale

If the liquid phase is an aqueous electrolyte solution, and the solid is a salt hydrate, the above treatment needs slight modification. Using rational mean activity coefficients, eqn [34] becomes:

$$\ln \left\{ \frac{x_B^v (1 - x_B)^n}{[1 + (v-1)x_B]^{n+v}} \right\} - \ln \left\{ \frac{n^n}{(n+v)^{n+v}} \right\} + \ln \left\{ \left(\frac{f_B}{f_B^*} \right)^v \left(\frac{f_A}{f_A^*} \right)^n \right\} \quad [47]$$

$$- \left[\frac{\Delta H_{AB}^* - T^* \Delta C_p^*}{R} \right] \left\{ \frac{1}{T} - \frac{1}{T^*} \right\} + \frac{\Delta C_p^*}{R} \ln(T/T^*)$$

where superscript * indicates the pure salt hydrate. If it is assumed that the activity coefficients follow the same temperature dependence as the right-hand side of eqn [47] (13-16), the thermochemical quantities on the right-hand side of eqn [47] are not rigorous thermodynamic enthalpies and heat capacities, but are apparent quantities only. Data on activity coefficients (9) in concentrated solutions indicate that the terms involving these quantities are not negligible, and their dependence on temperature and composition along the solubility-temperature curve is a subject of current research.

A similar equation (with $v = 2$ and without the heat capacity terms or activity coefficients) has been used to fit solubility data for some MOH-H₂O systems, where M is an alkali metal (13); enthalpy values obtained agreed well with known values. The full equation has been deduced by another method in (14) and applied to MCl₂-H₂O systems in (14) and (15). For a summary of the use of equation [47] and similar equations, see (14).

(2) Molality scale

Substitution of the mean activities on the molality scale in eqn [40] gives:

$$v \ln \left[\frac{\gamma_{\pm} m_B}{\gamma_{\pm}^* m_B^*} \right] - v(m_B/m_B^* - 1) - v(m_B(\phi - 1)/m_B^* - \phi^* + 1) \quad [48]$$

$$= G(T)$$

where $G(T)$ is the same as in eqn [47], $m_B^* = 1/nM_A$ is the molality of the anhydrous salt in the pure salt hydrate and γ_{\pm} and ϕ are the mean activity coefficient and the osmotic coefficient, respectively. Use of the osmotic coefficient for the activity of the solvent leads, therefore, to an equation that has a different appearance to [47]; the content is identical. However, while eqn [47] can be used over the whole range of composition ($0 < x_B < 1$), the molality in eqn [48] becomes infinite at $x_B = 1$; use of eqn [48] is therefore confined to solutions sufficiently dilute that the molality is a useful measure of composition. The essentials of eqn [48] were deduced by Williamson (17); however, the form used here appears first in the Solubility Data Series. For typical applications (where activity and osmotic coefficients are not considered explicitly, so that the enthalpies and heat capacities are apparent values, as explained above), see (18).

The above analysis shows clearly that a rational thermodynamic basis exists for functional representation of solubility-temperature curves in two-component systems, but may be difficult to apply because of lack of experimental or theoretical knowledge of activity coefficients and partial molar enthalpies. Other phenomena which are related ultimately to the stoichiometric activity coefficients and which complicate interpretation include ion pairing, formation of complex ions, and hydrolysis. Similar considerations hold for the variation of solubility with pressure, except that the effects are relatively smaller at the pressures used in many investigations of solubility (5).

(b) Solubility as a function of composition.

At constant temperature and pressure, the chemical potential of a saturating solid phase is constant:

$$\mu_{A_n B^*} = \mu_{A_n B}(\text{sln}) = n\mu_A + \mu_B \quad [49]$$

$$= (n\mu_A^* + v_+ \mu_+^{\infty} + v_- \mu_-^{\infty}) + nRT \ln f_A x_A$$

$$+ vRT \ln(\gamma_{\pm} m_{\pm} Q)$$

for a salt hydrate $A_n B$ which dissociates to water (A), and a salt (B), one mole of which ionizes to give v_+ cations and v_- anions in a solution in which other substances (ionized or not) may be present. If the saturated solution is sufficiently dilute, $f_A = x_A = 1$, and the quantity K_S in

$$\Delta G^{\infty} = (v_+ \mu_+^{\infty} + v_- \mu_-^{\infty} + n\mu_A^* - \mu_{AB}^*)$$

$$= -RT \ln K_S$$

$$\gamma_{\pm} = -\nu RT \ln(Q\gamma_{\pm}m_B) \quad [50]$$

is called the solubility product of the salt. (It should be noted that it is not customary to extend this definition to hydrated salts, but there is no reason why they should be excluded.) Values of the solubility product are often given on mole fraction or concentration scales. In dilute solutions, the theoretical behaviour of the activity coefficients as a function of ionic strength is often sufficiently well known that reliable extrapolations to infinite dilution can be made, and values of K_s can be determined. In more concentrated solutions, the same problems with activity coefficients that were outlined in the section on variation of solubility with temperature still occur. If these complications do not arise, the solubility of a hydrate salt $C_vA_v \cdot nH_2O$ in the presence of other solutes is given by eqn [50] as

$$\nu \ln(m_B/m_B(0)) = -\nu \ln(\gamma_{\pm}/\gamma_{\pm}(0)) - n \ln(a_A/a_A(0)) \quad [51]$$

where a_A is the activity of water in the saturated solution, m_B is the molality of the salt in the saturated solution, and (0) indicates absence of other solutes. Similar considerations hold for non-electrolytes.

Consideration of complex mixed ligand equilibria in the solution phase are also frequently of importance in the interpretation of solubility equilibria. For nomenclature connected with these equilibria (and solubility equilibria as well), see (19, 20).

The Solid Phase

The definition of solubility permits the occurrence of a single solid phase which may be a pure anhydrous compound, a salt hydrate, a non-stoichiometric compound, or a solid mixture (or solid solution, or "mixed crystals"), and may be stable or metastable. As well, any number of solid phases consistent with the requirements of the phase rule may be present. Metastable solid phases are of widespread occurrence, and may appear as polymorphic (or allotropic) forms or crystal solvates whose rate of transition to more stable forms is very slow. Surface heterogeneity may also give rise to metastability, either when one solid precipitates on the surface of another, or if the size of the solid particles is sufficiently small that surface effects become important. In either case, the solid is not in stable equilibrium with the solution. See (21) for the modern formulation of the effect of particle size on solubility. The stability of a solid may also be affected by the atmosphere in which the system is equilibrated.

Many of these phenomena require very careful, and often prolonged, equilibration for their investigation and elimination. A very general analytical method, the "wet residues" method of Schreinemakers (22), is often used to investigate the composition of solid phases in equilibrium with salt solutions. This method has been reviewed in (23), where [see also (24)] least-squares methods for evaluating the composition of the solid phase from wet residue data (or initial composition data) and solubilities are described. In principle, the same method can be used with systems of other types. Many other techniques for examination of solids, in particular X-ray, optical, and thermal analysis methods, are used in conjunction with chemical analyses (including the wet residues method).

COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A brief description of the data sheets has been given in the FOREWORD; additional explanation is given below.

Guide to the Compilations

The format used for the compilations is, for the most part, self-explanatory. The details presented below are those which are not found in the FOREWORD or which are not self-evident.

Components. Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The formula is given either in terms of the IUPAC or Hill (25) system and the choice of formula is governed by what is usual for most current users: i.e., IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered according to:

- (a) saturating components;
- (b) non-saturating components in alphanumerical order;
- (c) solvents in alphanumerical order.

The saturating components are arranged in order according to a 18-column periodic table with two additional rows:

Columns 1 and 2: H, alkali elements, ammonium, alkaline earth elements

3 to 12: transition elements

13 to 17: boron, carbon, nitrogen groups; chalcogenides, halogens

18: noble gases

Row 1: Ce to Lu

Row 2: Th to the end of the known elements, in order of atomic number.

Salt hydrates are generally not considered to be saturating components since most solubilities are expressed in terms of the anhydrous salt. The existence of hydrates or solvates is carefully noted in the text, and CA Registry Numbers are given where available, usually in the critical evaluation. Mineralogical names are also quoted, along with their CA Registry Numbers, again usually in the critical evaluation.

Original Measurements. References are abbreviated in the forms given by Chemical Abstracts Service Source Index (CASSI). Names originally in other than Roman alphabets are given as transliterated by Chemical Abstracts.

Experimental Values. Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm^{-3} for molar; etc. Both mass and molar values are given. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the other type of value (e.g., mole per cent) from computer calculations based on 1983 atomic weights (26).

Errors in calculations and fitting equations in original papers have been noted and corrected, by computer calculations where necessary.

Method. Source and Purity of Materials. Abbreviations used in Chemical Abstracts are often used here to save space.

Estimated Error. If these data were omitted by the original authors, and if relevant information is available, the compilers have attempted to estimate errors from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on the papers by Ku and Eisenhart (27).

Comments and/or Additional Data. Many compilations include this section which provides short comments relevant to the general nature of the work or additional experimental and thermodynamic data which are judged by the compiler to be of value to the reader.

References. See the above description for Original Measurements.

Guide to the Evaluations

The evaluator's task is to check whether the compiled data are correct, to assess the reliability and quality of the data, to estimate errors where necessary, and to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. A brief description of the evaluation sheets is given below.

Components. See the description for the Compilations.

Evaluator. Name and date up to which the literature was checked.

Critical Evaluation

(a) Critical text. The evaluator produces text evaluating all the published data for each given system. Thus, in this section the evaluator reviews the merits or shortcomings of the various data. Only published data are considered; even published data can be considered only if the experimental data permit an assessment of reliability.

(b) Fitting equations. If the use of a smoothing equation is justifiable the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets.

(c) Graphical summary. In addition to (b) above, graphical summaries are often given.

(d) Recommended values. Data are recommended if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are considered as tentative if only one set of measurements is

available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as doubtful if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value in those instances where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are rejected. However references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) References. All pertinent references are given here. References to those data which, by virtue of their poor precision, have been rejected and not compiled are also listed in this section.

(f) Units. While the original data may be reported in the units used by the investigators, the final recommended values are reported in S.I. units (1, 28) when the data can be accurately converted.

COMPONENTS:	EVALUATOR:
(1) Beryllium hydroxide; $\text{Be}(\text{OH})_2$; [13327-32-7]	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay-aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5], and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

An evaluation of the solubility of beryllium hydroxide in water and in various aqueous solutions.

The solubility of beryllium hydroxide depends on the crystalline form of the hydroxide. Solubility data are reported for three forms of the solid: an amorphous hydroxide, a metastable $\alpha\text{-Be}(\text{OH})_2$ and the stable $\beta\text{-Be}(\text{OH})_2$. At temperatures above 673 K the anhydrous oxide, BeO , is the stable form (1). The amorphous hydroxide forms on precipitation from a salt solution. In water it transforms to the less soluble metastable $\alpha\text{-Be}(\text{OH})_2$ (2, 6). In concentrated basic solution $\alpha\text{-Be}(\text{OH})_2$ spontaneously transforms to the thermodynamically stable $\beta\text{-Be}(\text{OH})_2$ (6).

The solubility of beryllium hydroxide has been determined either by direct analysis of the saturated solution or by a potentiometric method. The direct analysis of the saturated solution is used for the stable forms and the potentiometric method is used during precipitation of the amorphous form. Results from references (5, 11, 12, 14) were rejected because the temperature or the nature of the solid phase were ill-defined, or when the experimental details were insufficient to allow evaluation of the precision of the measurements.

1. Solubility of $\text{Be}(\text{OH})_2$ in water and in dilute solutions of acids and bases near room temperature.

Direct solubility measurements in dilute acid and base solutions have been reported around room temperature (1-3, 5, 9-13, 15). Because of the very low solubility in pure water, few direct solubility measurements were performed in this medium, and solubility values in pure water must be evaluated by extrapolation.

A. $\alpha\text{-Be}(\text{OH})_2$

Gilbert and Garrett (10) performed an extensive study at 298.15 K of the solubility of $\alpha\text{-Be}(\text{OH})_2$ in dilute solutions of acids (HCl , HClO_4) and base (NaOH). The nature of the solid phase was confirmed by X-ray analysis. The solubility increases with increase in either acid or base concentration as shown on Figs. 1 and 2. Schindler and Garrett (13) interpreted the data by the equilibria:

No significant differences in solubility were found for the two acidic media (HCl and HClO_4) which showed the absence of any complexation by the Cl^- ion.

The constants of the different equilibria were calculated by least squares analysis at 298.15 K and $I = 0$. The values obtained (13) were:

$$\log K_1 = 6.86 \pm 0.05$$

$$\log K_2 = 11.67 \pm 0.05$$

$$\log K_3 = -2.49 \pm 0.1$$

$$\log K_4 = -2.70 \pm 0.3$$

Equilibria 3 and 4 account for about 20% of the calculated solubility.

CRITICAL EVALUATION:

Figure 2. Solubility of α - $\text{Be}(\text{OH})_2$ in NaOH solutions (10)

COMPONENTS:	EVALUATOR:
(1) Beryllium hydroxide; $\text{Be}(\text{OH})_2$; [13327-32-7]	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay-aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5], and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

The K_1 and K_2 values allow calculation of the equilibrium constant of the overall equilibrium:

which is in good agreement with the value deduced by Lanza and Carpeni (21) of $K_{33} = 1.2 \times 10^{-9}$ from potentiometric measurements.

Baes and Mesmer (22) have reviewed the hydrolysis reactions of Be^{2+} in acidic solutions. In addition to the species considered by Garrett and Schindler (13) there is evidence of the species $\text{Be}_3\text{OH}^{3+}(\text{aq})$, $\text{BeOH}^+(\text{aq})$ and $\text{Be}(\text{OH})_2(\text{aq})$. When the equilibria:

and

are taken into account, the results of Gilbert and Garrett (10) lead to the solubility product:

$$K_{s0} = m(\text{Be}^{2+}) (m(\text{OH}^-))^2 / m^{03} \quad \log K_{s0} = -21.3.$$

The difference between activity and molality is ignored because of the low molalities involved. The solubility of $\alpha\text{-Be}(\text{OH})_2$ in pure water, assuming the presence of the aqueous species Be^{2+} , BeOH^+ and $\text{Be}(\text{OH})_2$ should be about

$$m(\text{Be}) = 5 \times 10^{-7} \text{ mol kg}^{-1}.$$

The value is doubtful because the hydrolysis constants are not precise. Bertin and Thomas (14) calculate $\log K_{12} = -11$ from their hydrolysis measurements. The value of $\log K_{11} = -5.4$ is only a rough estimate, because the data treatment ignored polynuclear species.

Solubility in the presence of sodium salts

The solubility measurements in the presence of chlorides, fluorides, nitrates, perchlorates and carbonates show a strong complexation by fluoride and carbonate (14, 17-20).

B. $\beta\text{-Be}(\text{OH})_2$

Fricke and Hume (6) measured the solubility of $\beta\text{-Be}(\text{OH})_2$ in aqueous NaOH solutions at 303 K. The $\beta\text{-Be}(\text{OH})_2$ was formed *in situ* by aging $\alpha\text{-Be}(\text{OH})_2$. From the variation of the solubility with time, it is possible to estimate the difference of Gibbs energy of formation of the two forms at 303 K:

$$\Delta_f G(\beta\text{-Be}(\text{OH})_2) - \Delta_f G(\alpha\text{-Be}(\text{OH})_2) \approx -2 \text{ kJ mol}^{-1}$$

This difference would lead to an approximate $\log K_{s0}^0 = -21.65$ for the $\beta\text{-Be}(\text{OH})_2$.

Fricke and Hume (6) pointed out the existence of the solid phase $\text{BeO} \cdot \text{NaOH} \cdot \text{H}_2\text{O}$ above 36.3 mass % NaOH. The data of Kolenkova *et al.* (15) are in qualitative agreement with Fricke and Hume's results.

C. Freshly precipitated Beryllium Hydroxide.

Solubility in water.

Oka (9) found a solubility of $1.4 \times 10^{-7} \text{ mol kg}^{-1}$ for the freshly precipitated hydroxide, but no details of the method are given. The value should be larger than the value for the more stable $\alpha\text{-Be}(\text{OH})_2$. This is evidence that the calculated value of 5×10^{-7} is probably too large. The value of $c_{\beta\text{e}} = 8 \times 10^{-6} \text{ mol dm}^{-3}$ found by the conductivity

<p>COMPONENTS:</p> <p>(1) Beryllium hydroxide; $\text{Be}(\text{OH})_2$; [13327-32-7]</p> <p>(2) Water; H_2O; [7732-18-5], and various aqueous solutions</p>	<p>EVALUATOR:</p> <table border="0"> <tr> <td>Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991</td><td>H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA</td></tr> </table>	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991	H. L. <p>CRITICAL EVALUATION:</p> <p>measurements of Remy and Kuhlman (5) is an order of magnitude higher than Oka's value and was rejected.</p> <p><i>Solubility of amorphous beryllium hydroxide in acidic solutions.</i></p> <p>Prytz (7, 8) studied the precipitation of $\text{Be}(\text{OH})_2$ by NaOH solutions at different beryllium salt concentrations. He interpreted his results assuming a solution species, $\text{Be}_2\text{O}^{2+}(\text{aq})$, and the equilibrium solid, $\text{Be}_2\text{O}(\text{OH})_2$, the hypotheses which best fitted his data. The mean value of the solubility product calculated from his results is:</p> $K_{s0} = c(\text{Be}^{2+})(c(\text{OH}^-))^2/c^{03} \quad \log K_{s0} = -20 \pm 1.$ <p>This is a tentative value because the results for the different beryllium salts differ, and the values depends on the hydrolysis equilibria used.</p> <p><i>Solubility of amorphous beryllium hydroxide in basic solutions.</i></p> <p>The solubility of freshly precipitated beryllium hydroxide in NaOH solution has been reported (1 - 3). The results are shown in Fig. 4 where they are compared with the solubility of $\alpha\text{-Be}(\text{OH})_2$ (10). Haber and Van Oordt (2) pointed out the importance of the decrease of solubility as the precipitate aged in NaOH solutions. Similar experiments were reported on KOH solutions by Bleyer and Kaufman (4) and are shown on Fig. 3. These two figures illustrate the difficulty of assessing the solubility values when starting with ill-defined materials.</p> <p><i>Solubility of beryllium hydroxide in four- and five-component systems.</i></p> <p>The solubility of amorphous $\text{Be}(\text{OH})_2$ was studied in aqueous NaClO_4 solutions with the addition of sodium bicarbonate (17), sodium carbonate (18), sodium bicarbonate and sodium fluoride (20) and citric acid (19). Quantitative comparison among the results is difficult as the crystalline form of the $\text{Be}(\text{OH})_2$ is not always the same. Nevertheless a strong complexation by both F^- and HCO_3^- is observed.</p> <p><i>SOLUBILITY AT HIGH TEMPERATURE.</i></p> <p>Solubilities of freshly precipitated and of "inactive" (probably α) forms were measured in dilute NaOH solutions up to 373 K (2). Solubilities of $\alpha\text{-Be}(\text{OH})_2$ in dilute NaOH and in dilute HNO_3 have been reported up to 573 K (16). The precision is poor and even the sign of the temperature coefficient is not clear. The solubility values at the high temperatures are judged doubtful.</p> <p>Soboleva <i>et al.</i> (26) Studied the solubility of α-beryllium oxide (bromellite [13598-21-5]) in $\text{NaOH} + \text{NaF} + \text{H}_2\text{O}$ at 423, 473 and 523 K. The authors treated the data to obtain equilibrium constants for the reaction</p> $\text{BeO}(\text{s}) + \text{H}_2\text{O}(\text{l}) + \text{F}^-(\text{aq}) = \text{Be}(\text{OH})_2\text{F}^-(\text{aq})$ <p>of 0.018 ± 0.011, 0.022 ± 0.003 and 0.012 ± 0.003, respectively, at the three temperatures.</p> <p>The solubility of BeO (bromellite) has also been studied at 573 K in aqueous HClO_4 and aqueous HF by Koz'menko <i>et al.</i> (27). The authors proposed a model, and derived equilibrium constant values from a weighted least squares method. See the data sheets for details.</p> <p><i>Comparison of these results with other evaluations.</i></p> <p>Both the NBS Thermodynamic Tables (23) and the Critical Stability Constant collection (24) contain evaluated data on the $\text{Be}(\text{OH})_2(\text{s}) + \text{H}_2\text{O}$ system. Some of these data are presented here for comparison. Without</p>

* values at 293 K. Values of questionable validity are given in ().

All species are in aqueous solution.

The *NBS Thermodynamic Tables* (23) contain a number of Gibbs energy of formation values from which we have calculated the following $\log K$ values at 298.15 K.

Equilibrium	$\log K$
$\alpha\text{-Be}(\text{OH})_2(\text{s}) = \text{Be}^{2+}(\text{aq}) + 2\text{OH}^-(\text{aq})$	-21.16
$\beta\text{-Be}(\text{OH})_2(\text{s}) = \text{Be}^{2+}(\text{aq}) + 2\text{OH}^-(\text{aq})$	-21.60
$\alpha\text{-Be}(\text{OH})_2(\text{s}) + 2\text{H}^+(\text{aq}) = \text{Be}^{2+}(\text{aq}) + \text{H}_2\text{O}$	6.66
$3\alpha\text{-Be}(\text{OH})_2(\text{s}) + 3\text{H}^+(\text{aq}) = (\text{BeOH})_3^{3+}(\text{aq}) + 3\text{H}_2\text{O}$	11.91
$3\text{Be}^{2+}(\text{aq}) + 3\text{H}_2\text{O} = (\text{BeOH})_3^{3+}(\text{aq}) + 3\text{H}^+(\text{aq})$	-8.58
$\alpha\text{-Be}(\text{OH})_2(\text{s}) + 2\text{OH}^-(\text{aq}) = \text{BeO}_2^{2-}(\text{aq}) + 2\text{H}_2\text{O}$	-2.65

The Gibbs energy difference for:

Crystal structures of beryllium oxide and hydroxide solids.

Characterization of the solid state in equilibrium with the saturated solution is an important part of any modern solubility study. The following information, mostly from the *Crystal Data Determinative Tables*, is neither complete nor evaluated, but is presented as a reminder of this important point.

Crystal Formula	Type	Density, $\rho/\text{Mg m}^{-3}$
[13598-21-5]; $\alpha\text{-BeO}$ (bromellite)	Hexagonal	3.008
[1304-56-9]; $\beta\text{-BeO}$ (beryllia)	Tetragonal	2.69
[13327-32-7]; $\alpha\text{-Be}(\text{OH})_2$	Tetragonal	-
[13327-32-7]; $\beta\text{-Be}(\text{OH})_2$	Orthorhombic	1.94

<p>COMPONENTS:</p> <p>(1) Beryllium hydroxide; $\text{Be}(\text{OH})_2$; [13327-32-7]</p> <p>(2) Water; H_2O; [7732-18-5]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Remy, H.; Kuhlmann, A.</p> <p><i>Z. Anal. Chem.</i>, <u>1924</u>, 65, 161-81.</p>
<p>VARIABLES:</p> <p>$T/K = 291$</p>	<p>PREPARED BY:</p> <p>H. Einaga Y. Komatsu</p>
<p>EXPERIMENTAL VALUES:</p> <p>Specific conductivity measured on conductivity water saturated with $\alpha\text{-BeO}$ at $20.0 - 20.2^\circ\text{C}$ was $1.795 \times 10^{-6} (\Omega \text{ cm})^{-1}$, which was converted to the value at 18°C of $1.729 \times 10^{-6} (\Omega \text{ cm})^{-1}$ by applying a temperature coefficient of 0.0190. After the correction for dissolved CO_2 (ref 1), solubility of $\text{Be}(\text{OH})_2$ was calculated from the specific conductivity by using the intrinsic specific conductivity of saturated $\text{Be}(\text{OH})_2$ solution of $3.29 \times 10^{-6} (\Omega \text{ cm})^{-1}$ to give 0.00020 g BeO per liter of solution. Solubility and solubility product of $\text{Be}(\text{OH})_2$ were calculated by the authors to be $8.1 \times 10^{-6} \text{ mol L}^{-1}$ and $2 \times 10^{-20} (\text{mol L}^{-1})^3$ respectively, under the assumption that $\text{Be}(\text{OH})_2$ dissociates completely in water.</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Conductivity water was saturated with BeO (specific conductivity, $1.258 \times 10^{-6} (\Omega \text{ cm})^{-1}$) in a conductivity cell by shaking at $20.0 - 20.2^\circ\text{C}$ for 1.5 to 2.5 hours. Specific conductivity of the resulting saturated solution was measured.</p> <p>NOTE: The specific conductivity unit, $(\Omega \text{ cm})^{-1}$, has been replaced by electrolytic conductivity, S cm^{-1}.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Beryllium hydroxide. $\text{Be}(\text{NO}_3)_2$ of high purity was dissolved in conductivity water followed by addition of freshly distilled NH_3 to precipitate $\text{Be}(\text{OH})_2$. After being washed with water, the precipitate was dissolved in acetic acid, the resultant beryllium(II) acetate was distilled at $330 - 331^\circ\text{C}$. It was dissolved in water to get a dilute aqueous solution from which $\text{Be}(\text{OH})_2$ was again precipitated by the addition of NH_3. The precipitate was heated at about 440°C to obtain BeO.</p> <p>(2) Water. Conductivity water of specific conductance $1.258 \times 10^{-6} (\Omega \text{ cm})^{-1}$ was used.</p>

16. ± 1.	3	20. ± 1.

The authors analyzed the data on the basis of the following equilibria:

The data were treated by a weighted least squares method. Additional details in the original paper. Calculated concentrations of $\text{Be(OH)}^+(\text{aq})$ and $\text{Be}^{2+}(\text{aq})$ were smaller than the measured beryllium concentration, and thus, they were neglected. The $\text{HF}_2^-(\text{aq})$ concentration was also negligably small.

The dilute concentrations could be used as molalities with negligible error.

AUXILIARY INFORMATION																													
METHOD/APPARATUS/PROCEDURE: The autoclave method was used under isothermal conditions. The α -BeO crystals and the acid solutions were sealed by welding in gold capsules of 5 or 10 mm diameter of 1 to 3.5 mL volume. The contents were adjusted so there was no more than 2 % vapor volume at 300°C. From 5 to 10 of these capsules were placed in a stainless steel autoclave, sealed and placed in a preheated oven for seven days. Preliminary studies showed equilibrium was established within 5 days. The autoclave was removed and cooled rapidly in cool water. The capsule contents were analyzed immediately for Be by an atomic absorption spectrometer. Either a flame or flame free method was used depending in part on the sample size. Results were checked in some cases by the weight loss of α -BeO.	SOURCE AND PURITY OF MATERIALS: (1) Bromellite (α -BeO). Crystals of 10-40 mg were washed with boiling aqua regia to eliminate inclusions containing V or Pb. After each experiment the crystals were washed with 5 % HF and inspected for cracks and inclusions. (2) Hydrogen fluoride. Prepared from special reagent. Conc. checked by pot. titrn. with F ⁻ electrode. (3) Water. Nothing specified. ESTIMATED ERROR: Temp.: Precision ±0.5 K. Soly.: See std. error of mean in table above. The total pressure, p = saturating vapor pressure.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
α-BeO was saturated with aqueous HNO ₃ solution in an autoclave at a specified temperature within ±5°C for 7 - 25 days. After equilibration, the aqueous phase was taken out, and dissolved Be ²⁺ was determined fluorometrically by using Morin [480-16-0] as a complexing reagent.		(1) α-Beryllium hydroxide. α-BeO (hexagonal crystal) was prepared by a hydrothermal method.	
		(2) Nitric acid. Chemically pure.	
		(3) Water. Twice distilled CO ₂ free water.	
		ESTIMATED ERROR:	
		Temp.: precision ± 5 K.	
		Soly.: see error reported by authors with molality values above.

$$\overline{K}_0 = 1.7$$

$$\overline{S}_0 = 2.1$$

$$K_{S0} = 2.9 \times 10^{-19}$$

Results were interpreted through the hydrolysis equation

followed by the precipitation reaction

The hydrolysis constant was defined by

$$K_0 = a_{\text{H}^+}^2 [(\text{BeOH})_2^{2+}] / [\text{Be}^{2+}]^2 = a_{\text{H}^+}^2 [\text{Be}_2\text{O}^{2+}] / [\text{Be}^{2+}]^2$$

and the solubility product by

$$K_{S0} = L = [\text{Be}^{2+}][\text{OH}^-]^2 = [\text{Be}_2\text{O}^{2+}]K_w^2 / [\text{H}^+]^2 = S_0 K_w^2.$$

Calculations were performed through the relations

(Be) = Total Be concentration

N = NaOH added, expressed in equivalents

$$K_w = 1.4 \times 10^{-14}$$

$$[(\text{BeOH})_2^{2+}] = (1/2) [N(\text{Be}) + [\text{H}^+]].$$

VARIABLES: $T/K = 292$	PREPARED BY: H. Einaga Y. Komatsu

EXPERIMENTAL VALUES:

Figure 1

The solubility product of $\text{Be}(\text{OH})_2$,

$$K_{\text{SO}} = ([\text{Be}^{2+}][\text{OH}^-]^2),$$

was calculated from experimental data of the concentration of $\text{Be}(\text{OH})_2$ and pH by the relation,

$$K_{\text{SO}} = c_1 \times K_w^2 \times 10^{2\text{pH}},$$

where K_w is the ion product of water (the value was not given in the text). Relation between K_{SO} and c_1 given in Figure 1 was analyzed by the relation,

$$-\log K_{\text{SO}} = -\log K_{\text{SO}}^0 + bc_1,$$

where b is a constant. K_{SO}^0 was estimated to be

$$-\log K_{\text{SO}}^0 = 25.7.$$

Solubility of $\text{Be}(\text{OH})_2$ in water at 19°C was calculated from K_{SO}^0 to be $1.71 \times 10^{-8} \text{ mol L}^{-1}$. In Figure 1, curves 1, 2, and 3 corresponds to initial concentration of beryllium(II) of 2×10^{-3} , 1×10^{-3} , and $0.5 \times 10^{-3} \text{ mol L}^{-1}$. Note that c_1 is assumed to be equal to concentration of Be^{2+} in the solution.

AUXILIARY INFORMATION**METHOD/APPARATUS/PROCEDURE:**

An aqueous solution containing $(0.5 - 2) \times 10^{-3} \text{ mol L}^{-1} \text{ BeSO}_4$ was hydrolyzed at 19°C under a constant pH value for 60 minutes (no description of the hydrolysis procedure). Be^{2+} in the solution was determined polarographically at -1.84 V (vs SCE) using 0.1 mol L^{-1} tetraethylammonium iodide as the supporting electrolyte, and pH was determined by a glass electrode pH meter.

SOURCE AND PURITY OF MATERIALS:

- (1) Beryllium hydroxide. Chemically pure.
- (2) Beryllium sulfate.
- (3) Water.

ESTIMATED ERROR:

No estimates possible.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A.: A one mol L ⁻¹ solution of BeSO ₄ is poured, drop by drop, into different KOH solutions until precipitation of Be(OH) ₂ . The OH ⁻ and Be concentrations are measured at the beginning of precipitation.		Nothing specified.	
B.: After precipitation of A, the precipitate stays 3 days in contact with the solution, and transforms itself into the form B.			
C.: C ₁ . Hydroxide B is filtered and dried. The solubility is measured after three days in contact with the KOH solution.		ESTIMATED ERROR:	
C ₂ . A commercial product (Merck) treated the same way as C ₁ .		No estimates possible.	
Be is analyzed gravimetrically as BeO after precipitation by NH ₄ OH. No other details given.		REFERENCES

AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:
Same method as used by the authors in a study of the solubility of BeO in aqueous NaOH and aqueous HNO ₃ (ref 1). Aqueous solutions were saturated with α-BeO in an autoclave at a specified temperature within ± 5 degrees for 7 - 25 days. After equilibration, the aqueous phase was sampled, and the dissolved Be ²⁺ was determined fluorometrically by use of Morin [480-16-0] as a complexing reagent. The authors treated these data to obtain equilibrium constants for the reaction: BeO(s) + H ₂ O(l) + F ⁻ (aq) = Be(OH) ₂ F ⁻ (aq) of 0.018±0.011, 0.022±0.003 and 0.012±0.003 at 150, 200 and 250°C, respectively.	(1) α-Beryllium oxide (bromellite). Artificial crystals. Hexagonal crystals prepared by a hydrothermal method. (2) Sodium fluoride. (3) Sodium hydroxide. Reagents specified chemically pure. (3) Water. Twice distilled CO ₂ free water. ESTIMATED ERROR: Temp.: Precision ± 5 K. Soly.: See average deviations in table above. REFERENCES: 1. Soboleva, G.I.; Tugarinov, I.A. Kalinina, V.F.; Khodakovskii, I.L. <i>Geokhimiya</i> 1977, (No. 7), 1013.

Additional experiments on the dependence of Be(OH) ₂ solubility on the fraction, α = [F ⁻]/([F ⁻] + [HCO ₃ ⁻]), gave a maximum at α = 0.5.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
β-Be(OH) ₂ was equilibrated with aqueous NaF solution of different concentrations containing NaHCO ₃ in a closed teflon vessel by shaking for 70 hours. The ionic strength of the aqueous solution was adjusted to 0.1 with NaClO ₄ before the equilibration. After 24 hours of standing, a supernatant portion of the saturated solution was taken out, and dissolved Be ²⁺ was determined fluorometrically by using Morin [480-16-0] or spectrophotometrically by using beryllon as complexometric reagents.		(1) β-Beryllium hydroxide. Prepared from analytical grade BeSO ₄ and NaOH in aqueous solution.	
		(2) Sodium fluoride. Chemically pure.	
		(3) Sodium bicarbonate. Chemically pure.	
		(4) Sodium perchlorate.	
		(5) Water. Distilled CO ₂ free water.

<p>CRITICAL EVALUATION:</p> <p>An evaluation of the solubility of magnesium hydroxide in water and in various aqueous solutions.</p> <p>The solubility of magnesium hydroxide in water and in aqueous solutions is reported in 35 publications. Some of them are very old and do not contain quantitative data, precise data, or enough experimental detail to evaluate. Such papers are only referenced and their data were not compiled.</p> <p>In aqueous solution the main equilibria which take place are:</p> <p>and</p> $\text{Mg}(\text{OH})_2(\text{s}) = \text{Mg}^{2+}(\text{aq}) + 2\text{OH}^{-}(\text{aq}) \quad K_{\text{so}}^{\circ} = [\text{Mg}^{2+}][\text{OH}^{-}]^2 \quad [1]$ $\text{Mg}^{2+}(\text{aq}) + \text{OH}^{-}(\text{aq}) = \text{MgOH}^{+}(\text{aq}) \quad [2]$ <p>The solubility is therefore a pronounced function of pH.</p> <p>The solubility of magnesium hydroxide is also dependent on its physical state. Both the precipitation of the hydroxide from salt solution and the hydration of MgO lead to the formation of an amorphous magnesium hydroxide designated in the literature as "labile" or "active". Aging the amorphous form changes it to the thermodynamically stable, well crystallized form, which is less soluble, called the "stable" or "inactive" form. The evolution toward the stable form may be slow, depending on temperature and chemical conditions. Thus, the solubility data may refer, in some cases, to some intermediate ill-defined state. The difference in solubility of these different forms may be perceptible in precise measurements.</p> <p>The crystalline magnesium hydroxide [1309-42-8] and the mineral brucite [1317-43-7] have the same structure (39). They are hexagonal with an a/c ratio of 1.5206 and a calculated density of $2.40 \times 10^3 \text{ kg m}^{-3}$.</p> <p>1. The solubility of magnesium hydroxide in water.</p> <p>Direct measurements of the solubility, obtained by saturating pure water with MgO or $\text{Mg}(\text{OH})_2$ and analyzing the supernatant liquid at equilibrium, are reported in a number of papers (1-3, 5, 7, 9-12, 14, 17, 23, 32). The $\text{Mg}(\text{OH})_2$ is determined by titration with an acid or by conductivity measurements. These measurements require total exclusion of CO_2 because of the strong influence of pH on the solubility. The papers of Fyfe (1) and Fresenius (2) are mostly of historical interest. Fyfe (1) did recognize that magnesium hydroxide solubility decreases with increasing temperature. See (45) for a summary of early solubility work.</p> <p>The starting material may be either the "active" hydroxide (2, 7, 10, 12, 14, 32) or the "inactive" hydroxide (17, 29). Several papers (5, 11, 23) give no indication of the form used. The "active" hydroxide results when MgO is used or when <i>in situ</i> precipitation from a salt solution is used. The "inactive" hydroxide results when the crystalline material is used. Bush (14) observed a decrease in solubility with time from 2.14×10^{-4} to $2.06 \times 10^{-4} \text{ mol dm}^{-3}$ at 302 K which he attributed to aging. The change is small compared to the scatter observed in other results which range from 1 to $4.5 \times 10^{-4} \text{ mol dm}^{-3}$ between 291 and 297 K (table 1). Nikolaev and Chelishcheva's result (23) is much larger and was rejected. No systematic trend with temperature or with starting material ("active" or "inactive") was observed in the values in table 1. The average of these results, excluding the two highest, gives an approximate value of the solubility around room temperature of:</p> $c_1 = (1.97 \pm 0.7) \times 10^{-4} \text{ mol dm}^{-3}$ <p>Travers and Nouvel (9) measured the magnesium hydroxide solubility over the 291 to 473 K temperature interval. They observed a linear decrease in solubility with increasing temperature up to 373 K.</p>

2. The magnesium hydroxide solubility product; measurements in ternary systems.

Since the solubility of $\text{Mg}(\text{OH})_2$ is very small and difficult to measure with precision, many studies are devoted to solubility measurements in solutions of different pH and ionic strengths. The experimental data can be analyzed to obtain the solubility product, K_{so}^0 , which in turn leads to an indirect value of the solubility in water. This kind of measurement is reported in a number of publications (6, 8, 9, 13, 16, 21, 22, 24, 29-31). All of the papers except the last one report data in the region of room temperature.

The available experimental data are total magnesium concentration, hydroxide ion concentration by titration or hydroxide ion activity by pH measurement. When the experimental precision permits, the $\text{Mg}^{2+}(\text{aq})$ concentration is obtained from the total magnesium concentration by taking into account the $\text{MgOH}^+(\text{aq})$ formation.

The thermodynamic solubility product, K_{so}^0 , is calculated by evaluation of the activity coefficients or by fitting the data and extrapolation to zero ionic strength. Different authors have used different methods to estimate the activity coefficients. Hostetler's evaluation (30) was based on a Debye-Hückel treatment fitted to the experimental data of $\gamma_{\pm}(\text{MgCl}_2)$ and $\gamma_{\pm}(\text{KCl})$ (36) for the activity coefficients. They were used to calculate K_{so}^0 from different sources and compare the results.

An improved treatment would require the estimation of the activity coefficients by full Pitzer equations fitted to each set of binary and ternary results. This is beyond the scope of this work, and it is not justified by the precision of most of the data.

<p>COMPONENTS:</p> <p>(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]</p> <p>(2) Water; H_2O; [7732-18-5] and various aqueous solutions</p>	<p>EVALUATOR:</p> <p>Irma Lambert H. L. Clever CEA/SCECF/SECA Department of B.P. 6 Chemistry 92265 Fontenay- Emory University aux-Roses Cedex Atlanta, GA 30322 FRANCE USA November, 1991</p>
<p>CRITICAL EVALUATION:</p> <p>A. $\text{Mg}(\text{OH})_2 + \text{NH}_3 + \text{NH}_4\text{X} + \text{H}_2\text{O} \quad \text{X} = \text{Cl}^-, \text{SCN}^-, \text{NO}_3^-, \text{CH}_3\text{CO}_2^-, \text{SO}_4^{2-}$</p> <p>Four publications (6, 8, 22, 29) report data on these systems. The $\text{Mg}(\text{OH})_2$ is equilibrated with the ammonia-ammonium salt solution. The saturated solutions are analyzed for Mg^{2+}, NH_3 and NH_4^+ and the OH^- concentration is calculated from the base ionization constant for $\text{NH}_3(\text{aq})$. Activity coefficients are neglected in these works, and the solubility product is calculated from $K_{s0}^\circ = [\text{Mg}^{2+}][\text{OH}^-]^2$ and the solubility from $c_1 = (K_{s0}/4)^{1/3}$.</p> <p>Loven (6) measured the magnesium hydroxide solubility as a function of ionic strength for five anions at 283 and 289 K. Since he did not find a systematic variation in the values with ionic strength, a more refined treatment, with estimation of activity coefficients, is not necessary. Loven calculated the solubility of $\text{Mg}(\text{OH})_2$ in water. The evaluator repeated the calculation using more recent (38) values of the aqueous ammonia ionization constant. The results are:</p> <p>With $K_b = 1.6 \times 10^{-5}$; $c_1 = 2.7 \times 10^{-4} \text{ mol dm}^{-3}$ at 283 K, and with $K_b = 1.7 \times 10^{-5}$; $c_1 = 2.8 \times 10^{-4} \text{ mol dm}^{-3}$ at 289 K.</p> <p>The data in (8, 22, and 29) were also recalculated by the evaluator using recent (38) K_b values. The results are summarized in table 2.</p> <p>B. $\text{Mg}(\text{OH})_2 + \text{H}_2\text{CO}_3 + \text{H}_2\text{O}$</p> <p>Kline (16) studied this system at 298 K as a function of CO_2 partial pressure (10.8 to 98.123 Pa). The $\text{Mg}(\text{OH})_2$ was precipitated from MgCO_3 solution. The saturated solution was analyzed for Mg^{2+} and HCO_3^- and the OH^- calculated from the dissociation constant of H_2CO_3. The thermodynamic solubility product was calculated by two methods: values of the concentration solubility product were calculated for each ionic strength and then extrapolated to zero ionic strength, or activity coefficients were estimated and combined with the solubility product of MgCO_3 and the ionization constants of H_2CO_3.</p> <p>The evaluator prefers the first more direct method. By this method Kline reports $\log K_{s0}^\circ = -11.57$. The evaluator repeated the calculation with a modern first ionization constant of H_2CO_3 ($\text{p}K_{a1} = 6.35$ at 298 K (38)) and obtained a value of $\log K_{s0}^\circ = -11.77$ which leads to a solubility value of $c_1 = 8 \times 10^{-5} \text{ mol dm}^{-3}$. Neither calculation corrected for the activity coefficient of the ions in pure water.</p> <p>C. $\text{Mg}(\text{OH})_2 + \text{MgCl}_2 + \text{H}_2\text{O}$</p> <p>Six papers (13, 15, 18, 19, 27, 30) report studies of this system, however, three of them (15, 18, 27) only report qualitative observations of the increase in $\text{Mg}(\text{OH})_2$ solubility with increasing MgCl_2 concentration.</p> <p>The complete phase diagram at 298 K is reported by Bury and Davies (19). They showed the existence of the three solid phases $\text{Mg}(\text{OH})_2$, $3\text{MgO} \cdot \text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ and $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. They also studied (20) the five-component system $\text{MgO} + \text{CaO} + \text{MgCl}_2 + \text{CaCl}_2 + \text{H}_2\text{O}$. In the region of the five-component system in which Mg^{2+} can be detected in solution only $\text{Mg}(\text{OH})_2$ and/or $\text{MgCl}_2 \cdot 3\text{MgO} \cdot 11\text{H}_2\text{O}$ are solid species. No solid Ca containing species is present.</p> <p>Hostetler (30) made the most careful studies of this system. He studied the solubility of magnesium hydroxide at 298 K as a function of ionic strength, aging and grain size.</p>	

COMPONENTS:	EVALUATOR:
(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5] and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

Hostetler followed the solubility during aging and correlated it to the grain size of the solid (see Figure 1). At a grain radius of about 50 nm the solid is in its stable state.

Hostetler (30) also measured pH and total magnesium concentration. He assumed two forms for the magnesium in solution

$$[\text{Mg}]_{\text{total}} = [\text{Mg}^{2+}] + [\text{MgOH}^+]$$

He evaluated the MgOH^+ contribution by a fitting his data to the equilibrium equations, and obtained the formation constant:

$$K_{11} = [\text{MgOH}^+]/[\text{Mg}^{2+}][\text{OH}^-] = 10^{2.6} = 4 \times 10^2 \text{ dm}^3 \text{ mol}^{-1}$$

He treated his data to obtain values of the thermodynamic solubility product and the solubility, both corrected for the MgOH^+ contribution, for both the stable and the active hydroxide. The results are:

Stable magnesium hydroxide: $\log K_{s0}^0 = -11.15$, $c_1 = 1.34 \times 10^{-4} \text{ mol dm}^{-3}$;

Active magnesium hydroxide: $\log K_{a0}^0 = -10.38$, $c_1 = 2.55 \times 10^{-4} \text{ mol dm}^{-3}$.

Gjaldbaek (13) carried out a similar set of experiments, but with a shorter time allowed for aging. The evaluator has recalculated the results using the same activity coefficients as Hostetler (30). The results are:

Stable magnesium hydroxide: $\log K_{s0}^0 = -10.8$, $c_1 = 1.7 \times 10^{-4} \text{ mol dm}^{-3}$;

Active magnesium hydroxide: $\log K_{a0}^0 = -9.2$, $c_1 = 6 \times 10^{-4} \text{ mol dm}^{-3}$.

The Hostetler results are preferred because of the longer time used to establish equilibrium.

D. $\text{Mg}(\text{OH})_2$ + Alkali Metal Salts + H_2O

Whitby (21) measured the solubility of magnesium hydroxide in seven aqueous alkali metal salt solutions at 298 K up to concentrations of 2 mol dm^{-3} . The results do not show a systematic correlation (figure 2).

Näsänen (24) measured the solubility of magnesium hydroxide as a function of ionic strength in aqueous NaCl and KCl solutions at 298 K. He measured the pH on precipitation of magnesium hydroxide from MgCl_2 solution, and took great care to avoid CO_2 , but did not take into account MgOH^+ . He extrapolated his results to zero ionic strength and obtained $\log K_{s0}^0 = -10.734$. The evaluator recalculated the constant using Hostetler's activity coefficients and MgOH^+ formation constant. The result was little changed, being:

$$\log K_{s0}^0 = -10.84 \text{ and solubility } c_1 = 1.6 \times 10^{-4} \text{ mol dm}^{-3}.$$

Horn (32) determined the solubility product at $I = 3 \text{ mol dm}^{-3}$ NaClO₄ at 298 K by an emf method. The physical state of the solid was not defined, although he did wait 3 to 7 days for his cells to come to equilibrium. He calculated $\log K_{s0}^0 = -11.14$ from his data. The compiler and evaluator recalculated and obtained $\log K_{s0}^0 = -11.86$. A thermodynamic constant cannot be calculated because the activity coefficients in this medium are not known.

Einaga (33) studied freshly precipitated $\text{Mg}(\text{OH})_2$ at $I = 1 \text{ mol dm}^{-3}$ NaNO_3 at 298 K. He found evidence of polynuclear species $\text{Mg}_2(\text{OH})_2^{2+}(\text{aq})$ and $\text{Mg}_3(\text{OH})_4^{2+}(\text{aq})$. Re-analysis of Hostetler's data taking into account the polynuclear species and their constants evaluated by Einaga did not change his thermodynamic solubility product at zero ionic strength.

COMPONENTS: (1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8] (2) Water; H_2O ; [7732-18-5] and various aqueous solutions	EVALUATOR: Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay-aux-Roses Cedex FRANCE November, 1991 H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

Figure 2. The solubility of $\text{Mg}(\text{OH})_2$ in various alkali metal salts solutions, 298 K, Whitby (21).

COMPONENTS:	EVALUATOR:	
(1) Magnesium hydroxide; $Mg(OH)_2$; [1309-42-8]	Irma Lambert CEA/SCECF/SECA B.P. 6	H. L. Clever Department of Chemistry
(2) Water; H_2O ; [7732-18-5] and various aqueous solutions	92265 Fontenay- aux-Roses Cedex FRANCE November, 1991	Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

Einaga's value in the $I = 1 \text{ mol dm}^{-3}$ medium is:

$$\log K_{s0} = -9.38$$

It is not possible to calculate a value of K_{s0}^0 from Einaga's experiment because of lack of knowledge of activity coefficients in the medium. However, using the same activity coefficients as Hostetler leads to:

$$\log K_{s0}^0 \approx -9.8$$

and the solubility in pure water of $c_1 \approx 3.4 \times 10^{-4} \text{ mol dm}^{-3}$.

Maigret (9) and Boryachek *et al.* (31) both studied the system $Mg(OH)_2 + NaCl + NaOH + H_2O$. The results in (9) are suprisingly high for a basic solution and are rejected. Boryachek *et al.* (31) observed the expected decrease in solubility with increasing NaOH concentration. The solubility of magnesium hydroxide in 310 g dm^{-3} NaCl is $3.7 \times 10^{-4} \text{ mol dm}^{-3}$ (31), not very different from the solubility in pure water shown in Tables 1 and 2.

The solubilities in pure water near room temperature estimated in this section from thermodynamic solubility product values are summarized in Table 2. Although the calculation from K_{s0}^0 values is questionable, the results show less scatter and there is an identifiable difference in the solubility of active and inactive magnesium hydroxide when compared with the values from direct solubility measurements in Table 1.

Hostetler's lower value, $c_1 = 1.34 \times 10^{-4} \text{ mol dm}^{-3}$ at 298 K, obtained under rigorous conditions is considered the best value of the solubility of inactive magnesium hydroxide in pure water. However, it is classed as a tentative value as it is an indirect result.

Because of the rapid change of the active state from freshly precipitated magnesium hydroxide toward the inactive state the active state is not well defined. It is only possible to say that the active magnesium hydroxide has a solubility 2 to 3 times larger than the inactive.

Table 2. Magnesium hydroxide solubility in water estimated from solubility products measured in ternary systems.

3. Solubility measurements above room temperature.

Lambert, Lefevre and Montel (34) studied the solubility of $\text{Mg}(\text{OH})_2$ at two ionic strengths from 293 to 573 K. The ionic strengths were I/mol kg⁻¹ = 0.01 (HCl) and 0.50 (NaCl or NaNO_3). The measurements were carried out in a titanium autoclave on a well-defined inactive $\text{Mg}(\text{OH})_2$ sample prepared by conditioning eight days at 573 K before the start of the measurements. The Mg^{2+} concentration was measured as a function of temperature. The pH was measured at room temperature and estimated at the other temperatures from the known variation of K_w with temperature. Side reactions of the solution with the walls of the autoclave induce some uncertainty in the pH calculations so no effort was made to evaluate the MgOH^+ formation constant. Comparison of the results in NaCl and NaNO_3 solutions showed evidence of MgCl^+ complex ion formation.

The authors (34) applied the Debye-Hückel treatment to obtain values of K_{s0}^0 . Although this type of calculation is uncertain at the highest temperatures of the experiment, these were the only data available to use to estimate the solubility of $\text{Mg}(\text{OH})_2$ in water for comparison with the direct measurements of Travers and Nouvel (17) over the 281 to 473 K interval. Only the results at low ionic strength were used after correction for MgCl^+ formation. K_{s0}^0 was recalculated using activity coefficients evaluated from the electrostatic term of Pitzer's equation as the virial terms were unknown:

$$\ln \gamma_{\pm} = -|Z_M Z_X| A^{\Phi} (I^{1/2}/(1 + bI^{1/2}) + (2/b) \ln (1 + bI^{1/2})) \quad [3]$$

with A^{Φ} values at the different temperatures from (37).

The solubility in water was evaluated from

$$m_1/\text{mol kg}^{-1} = (K_{s0}^0/4)^{1/3} \quad [4]$$

as the precision of the results was too poor to justify calculation of activity coefficients in pure water containing only the dissolved magnesium hydroxide.

COMPONENTS:

CRITICAL EVALUATION:

Figure 3. The solubility of $\text{Mg}(\text{OH})_2$ as a function of temperature, • Travers and Nouvel (17), o Lambert, Lefevre and Montel (34).

COMPONENTS:	EVALUATOR:
(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5] and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

The solubility results obtained from the data (34) at room temperature by the above procedure and by using Hostetler's activity coefficients differ by about 10 % which is less than the experimental precision.

The solubility values calculated as described above (34) and those of Travers and Nouvel (17) are compared in figure 3 and table 4. The results of (17) are up to 50 % larger at the lower temperatures than the values of (34). The difference may be due to insufficient aging of the solid $\text{Mg}(\text{OH})_2$ by Travers and Nouvel. The results were fitted to a three constant equation. At 291.15 K the average of five data points with a weight of 1 from (17) were used to avoid undue influence of the low temperature results from that work. The result is:

$$\ln (m_1/\text{mol kg}^{-1}) = 81.965 - 3432.07/(T/\text{K}) - 13.893 \ln (T/\text{K}) \quad [5]$$

$$s(m_1) = 1.83 \times 10^{-5} \text{ mol kg}^{-1}$$

No attempt was made to improve the fitting of the data by excluding values that were more than two standard deviations from the regression line as this would have excluded all of the high temperature data. The 298 K value is in reasonable agreement with the *tentative* value given earlier (about 24 % higher), assuming equality of concentration and molality in the dilute aqueous solution. Smoothed values from equation [5] are classed as *tentative* and are given in Table 5.

Table 4. Solubility of magnesium hydroxide in water as a function of temperature (17, 34) used in fitting equation [5].

T/K	Solubility of $\text{Mg}(\text{OH})_2$ $10^5 m_1/\text{mol kg}^{-1}$	Reference
291.15	18.9 (mean value)	17
308.15	16.9	17
318.15	15.0	17
343-348	11.8	17

511.15	0.96	34
554.15	0.46	34
573.15	0.18	34

4. Solubility measurements in supercritical water.

Walther (42) measured the solubility of brucite in supercritical water between 573 and 873 K and from 1 to 3 kbar total pressure. The concentration of Mg^{2+} decreases monotonically from 623 to 823 K at 1 kbar, but shows a sigmoidal behavior at 2 kbar. The solubility reaction

COMPONENTS:	EVALUATOR:
(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]	Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay-aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5] and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

Table 5. Tentative values of the solubility of $\text{Mg}(\text{OH})_2$ in water from Eqn [5].

$t/^{\circ}\text{C}$	T/K	Solubility $10^5 m_1/\text{mol kg}^{-1}$
0	273.15	19.5
25	298.15	16.6
50	323.15	13.2
75	348.15	10.0
100	373.15	7.44
125	398.15	5.39
150	423.15	3.85
175	448.15	2.72
200	473.15	1.92
225	498.15	1.35
250	523.15	0.95
275	548.15	0.67
300	573.15	0.47

is proposed to be:

where s.c. = supercritical.

Available thermodynamic data for Mg^{2+} support $\text{Mg}(\text{OH})^+$ as the dominant magnesium species in solution. The equilibrium constant for

was estimated from literature data. Values of pK at 1 kbar range from 5.38 at 623 K to 0.77 at 823 K, and at 2 kbar from 5.69 to 3.43 at the same temperatures. The calculations indicate $\text{Mg}(\text{OH})^+$ becomes the dominant magnesium species at neutral pH at temperatures above 633 K at 1 kbar and above 723 at 2 kbar. Walther's data are classed as tentative.

The early measurements of Poty *et al.* (44) at 773 K and 1 kbar were questioned by Walther because of the quenching procedure used. No data sheet was prepared for them.

5. Other ternary inorganic systems

A. $\text{Mg}(\text{OH})_2 + \text{MgSO}_4 + \text{H}_2\text{O}$

Kiessewetter (25) found that the influence of MgSO_4 on $\text{Mg}(\text{OH})_2$ solubility depends on the physical state of the hydroxide. The author gives no explanation of the data and no evaluation of its reliability can be made.

Danilov and co-workers (43) studied the system at 298 and 323 K. They show $\text{Mg}(\text{OH})_2$ to be the equilibrium solid phase up to 21.3 mass % MgSO_4 at 298 K and up to about 24.5 mass % MgSO_4 at 323 K. They show partial phase diagrams with regions of stability for the solids $3\text{MgO} \cdot \text{MgSO}_4 \cdot 11\text{H}_2\text{O}$ at 298 K and $5\text{MgO} \cdot \text{MgSO}_4 \cdot 8\text{H}_2\text{O}$ at 323 K. The solubility of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ was 27.60 mass % MgSO_4 at 298 K and the solubility of $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$ was 33.30 mass % at 323 K. The authors did not determine the $\text{Mg}(\text{OH})_2$ composition of the liquid phase and, thus, no data sheets were prepared.

COMPONENTS:

(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]

(2) Water; H_2O ; [7732-18-5] and various aqueous solutions

CRITICAL EVALUATION:

B. $\text{MgO} + \text{CrO}_3 + \text{H}_2\text{O}$

Revzin *et al.* (35) studied the system and showed the existence of $\text{MgCrO}_4 \cdot 5\text{H}_2\text{O}$.

C. $\text{MgO} + \text{B}_2\text{O}_3 + \text{H}_2\text{O}$

Nikolaev and Chelishcheva (23) studied the system and found that the successive equilibrium solids as mass % B_2O_3 increased were $\text{Mg}(\text{OH})_2$, $2\text{MgO} \cdot 3\text{B}_2\text{O}_3 \cdot 15\text{H}_2\text{O}$, $\text{MgO} \cdot 2\text{B}_2\text{O}_3 \cdot 9\text{H}_2\text{O}$ and $\text{MgO} \cdot 3\text{B}_2\text{O}_3 \cdot 7.5\text{H}_2\text{O}$.

D. $\text{MgO} + \text{H}_2\text{O}_2 + \text{H}_2\text{O}$

Makarov and Volnov (26) studied the system at 273 and 283 K. They found MgO to be the equilibrium solid only at 273 K and <0.43 mass % H_2O_2 . The other solids appearing in the system are $\text{MgO}_2 \cdot \text{H}_2\text{O}$, $\text{MgO}_2 \cdot 0.5\text{H}_2\text{O}$ and MgO_2 .

6. Ternary systems with an organic component

A. $\text{Mg}(\text{OH})_2 + \text{CH}_3\text{O} + \text{H}_2\text{O}$
 $\text{Mg}(\text{OH})_2 + \text{C}_2\text{H}_5\text{O} + \text{H}_2\text{O}$

Janković (28) studied the solubility of $\text{Mg}(\text{OH})_2$ in methanol + water mixed solvent up to 35.3 mass % methanol and in ethanol + water mixed solvent up to 21.6 mass % ethanol. The solubility of $\text{Mg}(\text{OH})_2$ decreased with increasing alcohol concentration with the ethanol showing a greater effect than the methanol. The solid phase was claimed to be $\text{Mg}(\text{OH})_2$.

B. $\text{Mg}(\text{OH})_2 + \text{C}_6\text{H}_{12}\text{O}_6(\text{glucose}) + \text{H}_2\text{O}$

Fleury (4) observed that glucose increases the solubility of $\text{Mg}(\text{OH})_2$ in water.

7. Comparison of the present results with other evaluations.

These values are presented for comparison; no effort has been made to judge one set of data against another.

Smith and Martell (40) give $\log K^0 = -11.15 \pm 0.2$ at 298.15 K. They also give formation constants at 298.15 K and ionic strength of 0 and 3 for:

Reaction	log K at 298.15 K and ionic strength:		
	0	3.0 mol dm ⁻³	
$\text{Mg}^{2+}(\text{aq}) + \text{OH}^-(\text{aq}) = \text{Mg}(\text{OH})^+(\text{aq})$	2.58 ± 0.0	1.85	" "
$4\text{Mg}^{2+}(\text{aq}) + 4\text{OH}^-(\text{aq}) = (\text{Mg}_4(\text{OH})_4)^{4+}(\text{aq})$	16.3	16.93	" "

The NBS *Thermodynamic Tables* (39) give Gibbs energy of formation data from which we calculate $\log K^0 = -11.25$ for $\text{Mg}(\text{OH})_2(\text{s})$ and $\log K = 2.58$ for the formation of $\text{Mg}(\text{OH})^+(\text{aq})$.

8. Crystal structure of magnesium hydroxide.

Characterization of the solid state in equilibrium with the saturated solution is an important part of any modern solubility study. The following information, mostly from the *Crystal Data Determinative Tables* (41), is neither complete or evaluated, but it serves as a reminder of this important point.

Crystal Formula	Type	Density, $\rho/\text{Mg m}^{-3}$
MgO ; (periclase [1317-74-4])	cubic	3.61
$\text{Mg}(\text{OH})_2$; (formed in boiling H_2O)	orthorhombic	-
$\text{Mg}(\text{OH})_2$; (normal form [1309-42-8])	hexagonal	2.40
$\text{Mg}(\text{OH})_2$; (brucite [1317-43-7])		

<p>COMPONENTS:</p> <p>(1) Magnesium hydroxide; $Mg(OH)_2$ [1309-42-8]</p> <p>(2) Water; H_2O; [7732-18-5] and various aqueous solutions</p>	<p>EVALUATOR:</p> <table border="0"> <tr> <td>Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991</td><td>H. 16.13 mg per liter of 2 mol per liter KOH.

These early studies were flawed because of the presence of carbon dioxide or the presence of bases from the glassware used, because of impurities in the magnesium hydroxide samples, and because sufficient time to attain equilibrium was not always used. They are rejected.

The papers listed below contain information on magnesium hydroxide containing aqueous solutions, but they were not used because they either contained no experimental data, no reliable data, data from other published sources, or they were preliminary accounts published in more detail later.

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: Equilibration for 24 hours, followed by filtration. No other experimental details given.	SOURCE AND PURITY OF MATERIALS: (1) Magnesium hydroxide. Basic magnesium hydroxide was precipitated from magnesium sulfate by carbonic acid and ammonia. The precipitate was dissolved in nitric acid and reprecipitated the same way in order to obtain a pure product. It was then decomposed to MgO by heating to constant weight in a platinum crucible.																
	ESTIMATED ERROR: No estimates possible.																
	REFERENCES:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
MgO was equilibrated with conductivity water for 3.75 - 48 hours. Solubility of Mg(OH) ₂ was determined for the saturated filtrate by a gravimetric method with evaporation of the solvent, by conductivity measurements, or by conductimetric neutralization titration with HCl and KOH solutions. Contamination by CO ₂ was avoided ultimately by the gravimetric method and the method of conductimetric titration. Influence of CO ₂ was corrected for in the calculation of solubility of Mg(OH) ₂ from the conductivity data in the method of conductivity measurements by taking equilibrium		(1) Magnesium hydroxide. MgO was calcined before use.	
		(2) Water. Conductivity water of approximately 1 x 10 ⁻⁶ S cm ⁻¹ was used for the preparation of the saturated solution.

METHOD/APPARATUS/PROCEDURE: Purified MgO was mixed with freshly distilled conductivity water at $29.0 \pm 0.1^\circ\text{C}$ for 8 to 20 hours. The resulting saturated solution was filtered, H_2SO_4 was added to the filtrate, and the solution was titrated potentiometrically with KOH solution to determine dissolved $\text{Mg}(\text{OH})_2$. Contamination of atmospheric CO_2 was avoided by using stoppered flasks and liquid paraffin. Care was taken during filtration not to carry away any residual $\text{Mg}(\text{OH})_2$ from the saturated solution.	SOURCE AND PURITY OF MATERIALS: (1) Magnesium hydroxide. MgO of Merck was dissolved in HNO_3 ; the resulting $\text{Mg}(\text{NO}_3)_2$ was recrystallized and ignited to MgO at 850°C . (2) Water. ESTIMATED ERROR: Temp.: precision $\pm 0.1\text{ K}$. Precision in the titration procedure was about 1.2 %. REFERENCES: 1. Gjaldbaek, J. K. <i>Z. Anorg. Allg. Chem.</i> <u>1925</u> , 144, 269.

The compiler calculated the K _{s0} values using the ammonia K _b value of 1.7 × 10 ⁻⁵ , and the author's relationship			
The relationship took no account of MgOH ⁺ formation. Only the solubility of Mg(OH) ₂ as simple ions and the dissociation of NH ₃ were considered.			
K _{s0} = 4K _b ² [Mg ²⁺] ³ /[NH ₄ ⁺] ² .			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE.		SOURCE AND PURITY OF MATERIALS:	
Pure Mg(OH) ₂ was prepared and an excess shaken with aqueous solutions of NH ₄ Cl and of NH ₄ NO ₃ of known initial concentrations. The saturated solutions were titrated with acid to a nitrophenol end point.		(1) Magnesium hydroxide. Prepared by addition of ammonia to a solution of MgSO ₄ .	
The ammonia concentration was obtained from the titration. The ammonium ion concentration was obtained by difference from the initial ammonium salt concentration, and the magnesium ion concentration was taken as 1/2 the ammonia concentration.		Nothing further specified.	
Mg(OH) ₂ + 2NH ₄ Cl = MgCl ₂ + 2NH ₄ OH		ESTIMATED ERROR:	
		No estimates possible.

EXPERIMENTAL VALUES:			
The solubility of $\text{Mg}(\text{OH})_2$ in aqueous $\text{NH}_3 + \text{NH}_4\text{Cl}$ at 18 and 22°C			
	$\text{Mg}(\text{OH})_2$	Remarks	
$t/^\circ\text{C}$	$10^4 c_1/\text{mol L}^{-1}$		
22	1.8	A. $\text{Mg}(\text{OH})_2$ precipitated in the absence of organic acids.	
	5.6	B. $\text{Mg}(\text{OH})_2$ precipitated in the presence of citric acid.	
	5.3	C. $\text{Mg}(\text{OH})_2$ precipitated in the presence of sodium tartrate.	
18	2.1	A. As A. above.	
	6.5	B. As B. above.	
	6.1	C. As C. above.	
The solutions at 18°C contained NH_3 , $c_2/\text{mol L}^{-1} = 0.0136$ and NH_4Cl , $c_3/\text{mol L}^{-1} = 0.0125$.			
The solubility product of $\text{Mg}(\text{OH})_2$ at 18°C was calculated from the relations:			
$K = [\text{NH}_4^+]^2/([\text{Mg}^{2+}][\text{NH}_4\text{OH}]^2)$, $K_b = [\text{NH}_4^+][\text{OH}^-]/[\text{NH}_4\text{OH}] = 1.75 \times 10^{-5}$ (18°C), and $K_{s0} = [\text{Mg}^{2+}][\text{OH}^-]^2 = K_b^2/K$. The analytical results for $[\text{NH}_3]$			
$(=[\text{NH}_4\text{OH}])$, $[\text{NH}_4^+]$ and $[\text{Mg}^{2+}]$ were used to obtain values for K_{s0} of 3.71×10^{-11} (cf. A.), 1.11×10^{-9} (cf. B.), and 9.00×10^{-10} (cf. C.).			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Procedure I. $\text{Mg}(\text{OH})_2$ was equilibrated at 22°C with CO_2 -free water for 8 h. The Mg^{2+} in the supernatant portion was determined by titration with standard HCl solution.		(1) Magnesium hydroxide. The $\text{Mg}(\text{OH})_2$ was precipitated from an aqueous solution containing 0.5 mol L^{-1} MgCl_2 , 0.25 mol L^{-1} NH_4Cl , 1.24 mol L^{-1} NH_3 , and $(0-3) \times 10^{-3}$ mol L^{-1} of either citric acid or sodium tartrate. The solution and precipitate were protected against CO_2 and allowed to stand 2-3 days at room temperature. The precipitate was washed with water and used without any drying procedure.	
Procedure II. $\text{Mg}(\text{OH})_2$ was equilibrated with an aqueous solution containing 0.0125 mol L^{-1} NH_4Cl and 0.0136 mol L^{-1} NH_3 by shaking 8 h at 18°C. The supernatant saturated solution was analyzed for NH_3 by titration with standard HCl solution and for Cl^- by Mohr's method. The $[\text{Mg}^{2+}]$ and $[\text{NH}_4^+]$ were calculated by difference by the materials balance requirement.		ESTIMATED ERROR:	
		No estimates possible.

<p>VARIABLES:</p> <p>$T/K = 298$</p>	<p>PREPARED BY:</p> <p>I. Lambert H. L. Clever</p>
<p>EXPERIMENTAL VALUES:</p> <p>ADDITIONAL COMMENTS AND/OR DATA:</p> <p>The authors used two samples of MgO. They were (1) "analytical reagent" grade, sulfur-free MgO (to specification GOST 4526-67), and (2) "pure" grade superlight MgO (to specification TU 6-09-2213-72). The authors state "since neither of the varieties of MgO used reacts with water, magnesium hydroxide cannot be formed under our experimental conditions." The Schreinemakers' method of residues confirms this by showing MgO to be the phase in equilibrium with the saturated solution in Series I.</p> <p>Series II experiments used both reagent grade and freshly precipitated Mg(OH)₂. The equilibrium solid is Mg(OH)₂. The solubility curves from Series I and II show good agreement.</p> <p>Neither series showed the presence of magnesium oxide chromates or basic chromates. The solid phases present were identified by X-ray diffraction.</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The solubility was studied by isothermal treatment in a thermostat at $(25 \pm 0.1)^{\circ}\text{C}$ until equilibrium was attained between the liquid and solid phases (0.5 to 3 h). The solutions were sampled after filtration or centrifugation. The saturated solutions were analyzed for both magnesium and chromium (VI). The magnesium was determined by titration with Trilon B [disodium salt of EDTA], and the chromium by reaction with ammonium iron (II) sulfate.</p> <p>The "wet residues" were also analyzed. Water was determined by either drying to constant weight or as the difference between the total weight and the weight of MgO and CrO₃. Agreement between the two procedures was good.</p> <p>The solid phases were determined graphically by Schreinemaker's method of residues. The solid phases were identified by X-ray diffraction.</p> <p>The paper also reports the solubility of pure MgCrO₄·5H₂O and MgCr₂O₇·6H₂O and 25°C.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Magnesium oxide. See additional comments above.</p> <p>(2) Magnesium hydroxide. Either analytical reagent grade (to specification MRTU 6-09-5084-68) MgO·0.97H₂O by analysis of freshly precipitated material.</p> <p>ESTIMATED ERROR:</p> <p>Sold. No estimates possible. Temp. ± 0.1 K (precision).</p> <p>REFERENCES:</p>

0.02	1.3	9.822	0.370	10.88
0.004	1.7	10.115	0.296	10.91
0.0008	2.45	10.336	0.206	10.98
0	3.25	10.653	0.268	10.92

Av. 10.99 ± 0.17

$$^a s_o = c_{\text{Mg}^{2+}} \cdot \gamma_{\text{Mg}^{2+}} \cdot a_{\text{OH}^-}^2$$

$$-\log \gamma_{\text{Mg}^{2+}} = k n (c)^{1/3}$$

where c = total ion concentration,

n = ionic charge of Mg^{2+} , and

k = a fitted constant.

The total magnesium ion concentration is calculated

$$c_{\text{Mg}^{2+}} = c_{\text{MgCl}_2} + c_{\text{Mg}(\text{OH})_2} - c_{\text{MgOH}^+}$$

The hydroxide ion activity is calculated from $a_{\text{H}^+} \cdot a_{\text{OH}^-} = 10^{-14.23}$ at 18°C .

$d \log (K_{s0}^\circ)/dT$ was determined to be 0.006 in the 0 - 35°C range for the inactive form of $\text{Mg}(\text{OH})_2$.

The solubility product of labile $\text{Mg}(\text{OH})_2$ in aqueous MgCl_2 at 18°C

MgCl_2 $c_2/\text{mol L}^{-1}$	pH	$-\log s_{s0}$
0.1	10.34	9.37
0.02	10.59	9.32
0.0049	10.90	9.18

$c_{\text{Mg}^{2+}} = c_{\text{MgCl}_2}$; pH is taken as the beginning of precipitation, and the remaining calculation is as in the former case.

NOTE: The compilers were unable to recalculate the values of $-\log \gamma$ in the tables from the data given.

<p>COMPONENTS:</p> <p>(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]</p> <p>(2) Magnesium chloride; MgCl_2; [7786-30-3]</p> <p>(3) Water; H_2O; [7732-18-5]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Gjaldbaek, J. K.</p> <p>Z. Anorg. Allgem. Chem. <u>1925</u>, 144, 145-68, 269-88.</p>

<p>EXPERIMENTAL VALUES:</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>I. Inactive modification of $\text{Mg}(\text{OH})_2$. 300 mg of $\text{Mg}(\text{OH})_2$ are mixed with 100 mL of MgCl_2 solution and the pH of the solution is measured continuously with a hydrogen electrode until a constant emf is reached (2 m to 2 h). The Mg^{2+} in the filtered saturated solution is determined by titration with $0.01 \text{ mol L}^{-1} \text{ HCl}$, and $0.01 \text{ mol L}^{-1} \text{ NaOH}$ using the hydrogen electrode as indicator. In order to evaluate c_{MgOH^+}, the hydrolysis constant, $a_{\text{MgOH}^+}/(a_{\text{Mg}^{2+}} \cdot a_{\text{OH}^-})$, was estimated so as to obtain agreement between the pH and the calculated hydroxide ion activity, $a_{\text{OH}^-} = \gamma_{\text{OH}^-} c_{\text{OH}^-}$. The hydroxide ion concentration was deduced from the titration, and the activity coefficient calculated from $-\log \gamma_{\text{OH}^-} = 0.2(c_{\text{ion}})^{1/3}$.</p> <p>II. Active (labile) modification of $\text{Mg}(\text{OH})_2$. Either metallic Mg was introduced into the MgCl_2 solutions, or NaOH was added to the MgCl_2 solution until precipitation. The pH is measured continuously and the highest value used in the solubility product calculation which is carried out in the same manner as for the inactive modification.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Magnesium hydroxide. Inactive form. Prepared by precipitation from MgCl_2 solution using an under-stoichiometric amount of NaOH in a CO_2 free environment. After three days the $\text{Mg}(\text{OH})_2$ was washed with distilled water until free of chloride ion. The final product contained only traces of carbonate.</p> <p>(2) Magnesium chloride. Solutions were prepared in distilled water taking care to avoid CO_2 contamination.</p> <p>(3) Water. Distilled, CO_2 free.</p> <p>ESTIMATED ERROR:</p> <p>Emf measurements: Accuracy better than 0.5 mV.</p> <p>REFERENCES:</p>

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A mixture of MgCl_2 , MgO , and H_2O was shaken in a thermostat at 25°C for 2 months until equilibrium had been established. After the equilibration the solid phase was filtered off through a fine sintered glass plate and the filtrate analyzed for Cl^- by the Volhard method. The wet solid was analyzed (results are in the paper but not given here) for Mg^{2+} by the gravimetric method as $\text{Mg}_2\text{P}_2\text{O}_7$ and for Cl^- by the Volhard method.		(1) Magnesium oxide. Prepared by heating MgCO_3 to 850°C . It contained about 0.3 mass % CaO .	
The values above are the mean of two concordant measurements.		ESTIMATED ERROR:	
The authors cite earlier papers (ref 1, 2) that were not successful in establishing the phase rule line of this system.		No estimates possible.

The solubility of $\text{Mg}(\text{OH})_2$ was calculated from the expressions for the ionization of ammonia and the solubility product of $\text{Mg}(\text{OH})_2$.			
$K_b = [\text{NH}_4^+][\text{OH}^-]/[\text{NH}_3]$, and $(\text{Mg}^{2+})[\text{OH}^-]^2 = K_{s0}^* = 4c^3$, where the last term applies to $\text{Mg}(\text{OH})_2$ in pure water as an ideal, completely ionized substance without association or hydrolysis. The author eliminated $[\text{OH}^-]$ from the two expressions, and solved for c . An ammonia ionization constant of 2.3×10^{-5} (ref 1) was used in the calculation.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:		
Solutions of magnesium chloride and ammonia were equilibrated for several days in stoppered bottles at ambient temperature. After filtering, the saturated solutions were evaporated, and the dry solid decomposed to MgO by heating in a platinum vessel which was weighed.	Nothing specified.		
The NH_3 is titrated with <i>o</i> -nitrophenol as the indicator. The NH_4^+ ion concentration is calculated as the difference between the initial NH_3 concentration and the final NH_3 concentration found by titration.	ESTIMATED ERROR:		
	No estimates possible.

The author calculated the solubility from the relations:				
c _{Mg(OH)2} = (c _{Mg} ²⁺ + [(1/2)K ₂ (c _{NH3})(c _{NH4+})] ²) ^{1/3} , and				
K ₂ = c _{NH4+} · c _{OH-} / c _{NH3} = 1.77 × 10 ⁻² (ref 1). The K ₂ value is used to calculate Mg(OH) ₂ concentration values from ref 2 and 3 as 2.9 × 10 ⁻⁴ at 10°C and 2 × 10 ⁻⁴ at 29°C mol L ⁻¹ , respectively.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The solubility of Mg(OH) ₂ in aqueous NH ₃ -NH ₄ Cl-MgCl ₂ solutions was determined by two methods. Method I. NH ₃ and NH ₄ Cl were added to aqueous MgCl ₂ solution. Method II. Solid Mg(OH) ₂ was shaken with aqueous NH ₄ Cl solution. The mixtures were shaken 2 - 7 days at 18.00 ± 0.02°C. Aliquots of the saturated supernatant aqueous phase were withdrawn by pipet to which filter paper had been attached. The saturated solutions were analyzed for Mg ²⁺ by titrimetry. Contamination with CO ₂ was carefully avoided. Paraffined flasks were used for the equilibration vessels.		(1) Magnesium hydroxide. Precipitated from aqueous MgCl ₂ solution with NaOH, filtered in CO ₂ free atm and dried at room temperature.		
		(2) Magnesium chloride		
		(4) Ammonium chloride. Both analytical grade, stated they were purified, but no details given.		
		ESTIMATED ERROR:

* NaOH used instead of $\text{Ba}(\text{OH})_2$.

** KCl added to increase the ionic strength.

*** Value recommended by the author, but as 11.15 ± 0.03.

Series A. Brucite. Author stated insufficient aging time was used, and possibly CO_2 contamination took place.

Series B. Brucite. Solutions possibly supersaturated because of insufficient stirring after proper aging.

Series C. Brucite. Carried out with continuous stirring in a CO_2 free atmosphere. pH vs. time confirmed aging time.

Series D. Used $\text{Mg}(\text{OH})_2$ precipitated in solution from $\text{Ba}(\text{OH})_2$ and MgCl_2 rather than Brucite. Conditions as in Series C.

$K_{s0}^* = a_{\text{Mg}^{2+}} \cdot a_{\text{OH}^-}^2$ where a = activity.

The magnesium ion activity coefficient, $\gamma_{\text{Mg}^{2+}}$, was calculated from the mean activity coefficients of MgCl_2 and KCl (ref 1).

Correction for MgOH^+ formation was carried out.

The solubility values are the sum of the calculated Mg^{2+} and MgOH^+ molalities. The author gave the table value as a concentration because there is negligible difference between molal and molar in water at these concentrations.																						
The last value in the table is one of the runs in series D on the previous page. The next to last value is from series A.																						
AUXILIARY INFORMATION																						
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:																					
Emf measurements were used to determine the pH of the cell: $\text{Ag}, \text{AgCl}/\text{KCl}/\text{sample sln}/\text{glass elec.}$ The symbol // represents the palladium junction of the commercial electrode which suppresses leakage of KCl during the long period of the experiment. The dissolved Mg^{2+} was determined gravimetrically with 8-quinolinol as the precipitating agent. The activity of the magnesium ion was calculated from its molality using activity coefficients either from published data (ref 1) or by calculation from Debye-Huckel equation. Nitrogen gas was bubbled through the suspension to keep the system CO_2 free.	(1) Magnesium hydroxide. Reagent grade $\text{Mg}(\text{OH})_2$ in the form of well crystallized brucite was used as received.																					
	(2) Magnesium chloride. Reagent grade purified by recrystallization.																					
	ESTIMATED ERROR:																					
	Accuracy of emf measurements: ± 0.02 pH units.

The solubility of Mg(OH) ₂ was calculated from the expressions for the ionization of ammonia and the solubility product of Mg(OH) ₂ .			
K _b = [NH ₄ ⁺][OH ⁻]/[NH ₃], and {Mg ²⁺ }[OH ⁻] ² = K _{so} [*] = 4c ³ , where the last term applies to Mg(OH) ₂ in pure water as an ideal, completely ionized substance without association or hydrolysis. The author eliminated [OH ⁻] from the two expressions, and solved for c. An ammonia ionization constant of 2.3 x 10 ⁻⁵ (ref 1) was used in the calculation.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Solutions of magnesium sulfate and ammonia were equilibrated for several days in stoppered bottles at ambient temperature. After filtering, the saturated solutions were evaporated, and the dry solid decomposed to MgO by heating in a platinum vessel which was weighed.		Nothing specified.	
The NH ₃ is titrated with o-nitrophenol as the indicator. The NH ₄ ⁺ ion concentration is calculated as the difference between the initial NH ₃ concentration and the final NH ₃ concentration found by titration.		ESTIMATED ERROR:	
		No estimates possible.

---	--

EXPERIMENTAL VALUES:

Solubility product of $\text{Mg}(\text{OH})_2$, K_{S0} , where

$$K_{\text{S0}} = [\text{Mg}^{2+}][\text{OH}^-]^2 = [\text{Mg}^{2+}] \cdot h^{-2} \cdot K_w^2,$$

was determined under the condition of the coexistence of the freshly precipitated amorphous $\text{Mg}(\text{OH})_2$ in 1.0 mol L^{-1} aqueous NaNO_3 solution from emf measurement for h , where $h = [\text{H}^+]$, with K_w of $1 \times 10^{-13.80}$ and from saturated concentration of $\text{Mg}(\text{II})$ from the data depicted in Figure 1. The graphical analyses carried out according to the relations are as follows:

$$\log G = \log 2(1 + \beta_{22}K_{\text{S0}}K_w^{-2} + \beta_{34}K_{\text{S0}}^2K_w^{-4})K_{\text{S0}}K_w^{-2} + 2\log h$$

$$G = 2C_{\text{Mg},\text{sol}} - (C_{\text{OH}} - [\text{OH}^-])$$

$$\beta_{22} = [\text{Mg}_2(\text{OH})_2^{2+}] \cdot h^2 / [\text{Mg}^{2+}]^2 = 10^{-21.07 \pm 0.10} \quad (\text{ref 1})$$

$$\beta_{34} = [\text{Mg}_3(\text{OH})_4^{2+}] \cdot h^4 / [\text{Mg}^{2+}]^4 = 10^{-39.16 \pm 0.10} \quad (\text{ref 1})$$

The result is

$$\log K_{\text{S0}} = -9.38 \pm 0.10$$

at 25°C in 1.0 mol L^{-1} NaNO_3 solution.

Solid Phases: A $\text{Mg}(\text{OH})_2$

B $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$

NOTE: The Mg^{2+} and the HCO_3^- were determined directly. The CO_3^{2-} was calculated by $m_{\text{CO}_3^{2-}} = m_{\text{Mg}^{2+}} - (1/2)m_{\text{HCO}_3^-}$. The total ionic strength is from the molalities of Mg^{2+} , HCO_3^- and CO_3^{2-} . The hydroxyl ion molality was found from the bicarbonate molality, the carbon dioxide partial pressure, the value of Henry's constant for CO_2 , and the ionization constants of H_2CO_3 .

The transition pressure between $\text{Mg}(\text{OH})_2$ and $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ at 25°C is 0.0004 atm. carbon dioxide.

The solubility product of $\text{Mg}(\text{OH})_2$ was obtained from the data by by two approaches. Approach I. Values of $m_{\text{Mg}^{2+}} \cdot m_{\text{OH}^-}^2$ calculated from the table above were extrapolated to zero ionic strength to give a value of $K_{s0}^* = 2.7 \times 10^{-12}$.

AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE: Solutions of calcium bicarbonate and magnesium bicarbonate are precipitated by Ca(OH) ₂ solutions. Concentrations are not specified. After precipitation the Mg(OH) ₂ and CaCO ₃ in the supernatant liquid are titrated with H ₂ SO ₄ (0.02 mol L ⁻¹). Samples are taken at different times until equilibrium is reached. The Mg(OH) ₂ concentration is found by subtracting the base concentration obtained in a similar experiment with CaCO ₃ alone.	SOURCE AND PURITY OF MATERIALS: Nothing specified. ESTIMATED ERROR: No estimates possible. The colloidal nature of the precipitate may give too large results. REFERENCES:

The data in tables 2 and 3 allows calculation of the complexation constant, $K_{c1} = [\text{MgCl}^+]/([\text{Mg}^{2+}][\text{Cl}^-])$. The data from tables 1 and 2 (table 1 corrected for complexation by Cl^-) are used to calculate the $\text{Mg}(\text{OH})_2$ solubility product, $K_{s0} = a_{\text{Mg}^{2+}} \cdot a_{\text{OH}^-}^2$ at each temperature. (continued on next page)

<p>COMPONENTS:</p> <p>(1) Magnesium hydroxide; $\text{Mg}(\text{OH})_2$; [1309-42-8]</p> <p>(2) Hydrochloric acid; HCl; [7647-01-0] or Sodium chloride; NaCl; [7647-14-5] or Sodium nitrate; NaNO_3; [7631-99-4]</p> <p>(3) Water; H_2O; [7732-18-5]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Lambert, I.; Lefevre, A.; Montel, J.</p> <p><i>Presented at the Eighth International CODATA Conference: Data for Science and Technology, Jachranka, Poland 1982.</i></p> <p><i>Water chemistry and corrosion problems in nuclear power plants. I is ionic strength. Solubility products are av. of two measurements.			
The thermodynamic value of the solubility product, K_{s0}° , was found by fitting the data to the Debye-Hückel equation in the form:			
$-\log K_{s0} = -\log K_{s0}^\circ + 3.04 I^{1/2}/(1 + a I^{1/2}) - B I$. The result is			
$-\log K_{s0}^\circ = 10.734$ or $K_{s0}^\circ = 1.84 \times 10^{-11}$			
NOTE: Earlier data (1) were regarded as erroneous by the author because he did not consider the effects of dissolved CO_2 . Additional experiments at known CO_2 partial pressures are reported.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Aqueous solutions of MgCl_2 contain- ing either NaCl or KCl were titrated with either aqueous NaOH or KOH , and the pH change was fol- lowed during the titration by emf measurements (1). The poten- tiometric titration curves were analyzed to obtain the $\text{Mg}(\text{OH})_2$ solubility product, K_{s0} . Results were obtained in the absence of CO_2 . Controlled additions of CO_2 were made, and the influence of CO_2 interpreted by taking MgHCO_3^+ for- mation into account.		Alkali hydroxide solutions were stored over barium hydroxide, and handled at low temperature in order to avoid CO_2 .	
		ESTIMATED ERROR:	
		No description, but precision in $\log K_{s0}$ may be estimated to be less than ± 0.02 log units.

4.00	2.63	1.37	16.56	16.86

Av. 16.58 ± 0.06

$H = [\text{H}^+]_{\text{init}}$, $h = [\text{H}^+]_{\text{eq}}$, $B = [\text{Mg}_{\text{tot}}]_{\text{eq}}$, $b = [\text{Mg}^{2+}]_{\text{eq}}$,
 $K'_{s0} = [\text{Mg}^{2+}][\text{H}^+]^{-2}$, $K_{11} = [\text{Mg}^{2+}][\text{OH}^-]$, $K_{s0} = [\text{Mg}^{2+}][\text{OH}^-]^2$, and
 $K_w = [\text{H}^+][\text{OH}^-] = 10^{-14.22}$. $[\text{Mg}^{2+}]$ was evaluated by $b = H - B$.

Lack of constancy of K'_{s0} from B is attributed to MgOH^+ formation. The formation constant is evaluated by $\log K_{11} = \log (B-b) + \log (b \cdot \text{OH}^-)$. Values of the solubility product and association constant in 3 mol L^{-1} aqueous NaClO_4 were calculated to be $\log K_{s0} = -11.14 \pm 0.07$ and $\log K_{11} = 4.88 \pm 0.07$.

AUXILIARY INFORMATION

METHOD/Apparatus/PROCEDURE:

Emf measurements were made on the cell, $\text{Ag}, \text{AgCl} // 2.99 \text{ mol L}^{-1} \text{NaClO}_4, 0.010 \text{ mol L}^{-1} \text{NaCl} // 3.00 \text{ mol L}^{-1} \text{NaClO}_4 // \text{sample at } 3.00 \text{ mol L}^{-1} \text{NaClO}_4 // \text{AgCl}, \text{Ag}$. The emf of the cell is $E = E^\circ + 59.16 \log h - 16.7h$ (ref 1). Standing 3 to 7 days were required to attain equilibrium. The dissolved Mg^{2+} was determined complexometrically. The solubility product was calculated from the values of h and $[\text{Mg}^{2+}]$ in the 3 mol L^{-1} NaClO_4 solution.

SOURCE AND PURITY OF MATERIALS:

(1) Magnesium hydroxide. Prepared by precipitation from aqueous solution containing Mg^{2+} and an alkali hydroxide. Analytical grade reagents were used as received.

ESTIMATED ERROR:

Emf: Accuracy ± 0.2 mV.

CRITICAL EVALUATION:

An evaluation of the solubility of calcium hydroxide in water and in various aqueous solutions.

Calcium hydroxide solubility measurements in water and aqueous solutions have been reported in 61 publications. Calcium hydroxide is a sparingly soluble strong base. The solubility equation, relative to complete ionization, is

The solubility equilibrium refers to the completely ionized state and clearly depends on pH.

The solubility also depends strongly on the physical state of the solid: aging of the amorphous hydroxide obtained either by precipitation or by CaO hydration leads to a thermodynamically well defined compound, which is crystalline and less soluble than the amorphous form. The crystalline form is hexagonal with an a/c ratio of 1.3660 and a calculated density of 2.244 Mg m^{-3} (64). It is therefore necessary to take into account the physical state of $\text{Ca}(\text{OH})_2(\text{s})$ in the comparison of experimental results.

1. The solubility of calcium hydroxide in water.

Twenty publications (1-4, 7, 11, 12, 17, 23, 28, 29, 31, 36-38, 44, 45, 48, 49, 51, 53, 54) are devoted to the study of the solubility of calcium hydroxide in water. Another 17 papers (5, 6, 8, 9, 14, 15, 18, 20, 24, 32, 33, 35, 42, 52, 58, 60) are concerned with a study of ternary systems, but also report solubility values in water. A critical review of the literature solubility data up to 1960 was carried out by Greenberg and Copeland (51). A review of work prior to 1920 is to be found in Mellor (71).

Results from three papers (4, 28, 54) were rejected. Shipley and McHaffie (28) found solubilities lower by a factor of 2 than the mean value from other publications. Koudelka's values (54) were for systems that did not reach equilibrium, and Shenstone and Cundall (4) were the only workers to report an increase in calcium hydroxide solubility with temperature.

The method generally used is equilibration of $\text{Ca}(\text{OH})_2(\text{s})$ with water, and analysis of the supernatant solution for calcium by gravimetry or complexometry, or acidimetry of the $\text{Ca}(\text{OH})_2(\text{aq})$. The results were classified, as much as possible, according to the state of the solid hydroxide: aged (33, 36, 44, 48, 49, 52); fresh, obtained by *in situ* hydration of CaO (2, 7, 12, 17, 31, 38); and undefined. When it was not possible to define the initial state of the hydroxide, the results were rejected.

At 298.15 K, the mean solubility values are:

"aged" calcium hydroxide $m [\text{Ca}(\text{OH})_2] = 2.02 \times 10^{-2} \text{ mol kg}^{-1}$
 $s(m) = 2.5 \times 10^{-4} \text{ mol kg}^{-1}$, and

"fresh" calcium hydroxide $m [\text{Ca}(\text{OH})_2] = 2.09 \times 10^{-2} \text{ mol kg}^{-1}$
 $s(m) = 1 \times 10^{-3} \text{ mol kg}^{-1}$.

The greater standard deviation for the "fresh" state is probably related to a poor definition of that state, which is unstable by nature. The difference in solubility is not significant.

The difference between the solubility of the "fresh" and "aged" calcium hydroxide decreases as the temperature increases. This is probably due to a faster rate of aging of the amorphous form at the higher temperatures.

CRITICAL EVALUATION:

The solubility data at 303 K and higher temperatures were fitted to an equation of the type:

$$\ln (m_1/\text{mol kg}^{-1}) = A_1 + A_2/(T/\text{K}) + A_3 \ln (T/\text{K}) + A_4 (T/\text{K})$$

The fourth term was not required for this system. During the fitting procedure, if the residual error between the observed and calculated molality, Δm , was larger than twice the standard deviation ($s(m)$) about the regression line for all m , the value was rejected, and the fitting procedure was started again.

As the difference between the solubility of "fresh" and "aged" calcium hydroxide was small and decreased as the temperature increased, the first fitting trial used all of the data at temperatures of 303 K and higher. Applying the procedure described above it was found that all of the rejected data were for "fresh" calcium hydroxide. Therefore it was decided to apply the fitting to only the "aged" calcium hydroxide data given in Table 1. The best fitting was obtained with the three-parameter equation:

$$\ln (m_1/\text{mol kg}^{-1}) = 86.1534 - 3492.14/T(\text{K}) - 13.7494 \ln (T/\text{K}) \quad [2]$$

which has a standard error of estimate over the range 273.15 to 623.15 K of

$$s(m) = 1.7 \times 10^{-4} \text{ mol kg}^{-1}.$$

Solubilities calculated by means of the equation are given in Table 2. Solubility values between 273 and 573 K are *recommended*. Values above 573 K, where the solubility values become the order of magnitude of the standard error, are *tentative*.

Table 2. Smoothed (recommended) values of the solubility of "aged" calcium hydroxide as a function of temperature.

(2) Water; H_2O ; [7732-18-5] and various aqueous solutions			

CRITICAL EVALUATION:

2. The solubility of calcium hydroxide in supercritical water.

Walther (67) measured the solubility of portlandite, $\text{Ca}(\text{OH})_2$, [12177-68-3] in supercritical water between 573 and 873 K at pressures between 1 and 3 kbar. He found that at constant pressure the solubility decreases as temperature increases. Thus at 2 kbar he states the log molality of calcium is -2.34, -2.71, -3.18 and -4.18 at temperatures of 573, 673, 773 and 873 K, respectively. The solubility at constant temperature increases with increasing pressure. Thus, at 773 K the log molality of calcium is -4.40, -3.18 and -2.65 at pressures of 1, 2 and 3 kbar, respectively. (Note that the trends are mis-stated in the abstract of the paper).

The author assumed $\text{Ca}^{2+}(\text{aq})$ to be the dominant calcium species and used literature thermodynamic data to calculate the distribution of species. The solutions apparently contain no significant concentrations of either $\text{Ca}(\text{OH})^+(\text{aq})$ or $\text{Ca}(\text{OH})_2(\text{aq})$. The calculated pH is 2 units greater than neutral and the solubility reaction is thought to be

where S.C. stands for supercritical. There are no other data on the system and the results are classed as tentative.

3. Ternary Inorganic Systems.

Five publications report solubility measurements in basic medium: NH_3 (37), LiOH (53, 55), NaOH (11, 44), KOH (44).

Results obtained at 293 K in NaOH solutions by d'Anselme (11) and by Fratini (44) are in fair agreement up to 0.1 mol dm^{-3} NaOH . The NaOH results do not differ from the results in KOH solutions (44) in the same concentration range. The solubility decreases with increasing hydroxide ion concentration as expected from the equilibrium equation [1]. The calcium hydroxide solubility at 293 K in the 0 to 0.1 mol dm^{-3} NaOH or KOH range is fitted to the quadratic equation:

$$c_1/\text{mol dm}^{-3} = 0.02056 - 0.2993 c_2/\text{mol dm}^{-3} + 1.4457 c_2^2/\text{mol dm}^{-3} \quad [3]$$

with a standard deviation in concentration of $s(c_1) = 1.4 \times 10^{-3}$ mol dm^{-3} .

The decrease of solubility with increasing base concentration is much less for LiOH and NH_4OH than for the NaOH and KOH . A quantitative comparison is not possible because of the differences in experimental conditions.

Measurements up to 373 K in aqueous NaOH and up to 423 K in aqueous LiOH show a negative temperature coefficient of solubility. Again no quantitative comparison or evaluation can be made because of the differences in experimental conditions.

Several studies (8-9, 14, 18, 33, 42, 52, 56, 58) are concerned with ionic strength effects on the solubility of "aged" calcium hydroxide in which an alkali metal salt is used to adjust the ionic strength. Cabot (8) observed a solubility increase in the presence of alkali metal salts which was of greater magnitude with Na^+ than with K^+ salts. Johnston and Grove (33) compared the effect of a number of salts on the solubility at 298.15 K relative to the solubility in pure water. They observed the solubility increase for cations is in the order $\text{Cs}^+ < \text{K}^+ < \text{Na}^+ < \text{Li}^+$ and for anions the order of increase is $\text{ClO}_4^- < \text{I}^- < \text{ClO}_3^- < \text{BO}_2^- < \text{Cl}^- < \text{NO}_3^- = \text{NO}_2^- < \text{CH}_3\text{CO}_2^-$. These comparisons are shown in figures 1 and 2.

Yeatts and Marshall (52) carried out a detailed study of the influence of NaNO_3 on the solubility of calcium hydroxide over the 273 - 623 K temperature range. They evaluated the thermodynamic solubility product constant ($K_{s0}^\circ = (4m_1\gamma_+/m_0)^3$) at each temperature from their results. The mean ionic activity coefficients were evaluated from an extended Debye-Hückel equation fitted to their data at each temperature. The solubility product was fitted to the equation:

$$\log (K_{s0}^\circ) = -25.7085 - 530.49/(T/\text{K}) + 12.9722 \log (T/\text{K}) - 0.032331 (T/\text{K}) \quad [4]$$

Standard thermodynamic relations were used to derive the thermodynamic functions reported in table 4 below.

$$\Delta G^\circ = -RT \ln K_{s0}^\circ$$

$$\Delta H^\circ = RT^2(\partial \ln K_{s0}^\circ / \partial T)_p$$

$$\Delta S^\circ = (\Delta H^\circ - \Delta G^\circ)/T$$

$$\Delta C_p^\circ = (\partial \Delta H^\circ / \partial T)_p$$

The results depend on the choice of equation for the activity coefficients. As Yeatts and Marshall evaluated their activity coefficients by a Debye Hückel extended equation fitted to their own data at each temperature their results are considered reliable.

Only Yeatts and Marshall report solubility measurements above 373 K. Between 273 and 373 K there are a number of reliable solubility values of "aged" calcium hydroxide. While these could be analyzed to obtain more reliable values of the thermodynamic solubility product and thermodynamic function at the lower temperatures, this would require a careful evaluation of the activity coefficients by, for example, the Pitzer equations fitted to each set of results for the binary and ternary systems, a treatment that is beyond the scope of this work.

The measurements of Komar and Vovk (56, 58) in aqueous KCl and NaCl are in good agreement with the results of Johnston and Grove (33) up to a chloride concentration of 1 mol dm^{-3} and are slightly lower at the higher ionic strengths. Dschorbenadse *et al.*'s results (42) in aqueous NaCl are much higher. No explanation for the higher results could be found by study of their method and the results are rejected.

Additions of ammonium chloride, as measured by Noyes and Chapin (9), causes a larger increase in calcium hydroxide solubility than the other 1-1 electrolytes. (The solubility at $0.04 \text{ mol dm}^{-3} \text{ NH}_4\text{Cl}$ is about twice the value in pure water). It is not possible to evaluate this single observation. The effect is probably related to the acid nature of the aqueous ammonium ion.

C. $\text{Ca}(\text{OH})_2 + \text{CaCl}_2 + \text{H}_2\text{O}$

Calcium hydroxide solubility data in this system have been reported in nine papers (5, 6, 19, 25, 26, 30, 46, 60, 70) in the 273-373 K temperature range. The whole temperature and concentration range was not covered in all papers so that only partial comparisons can be performed. All authors started with $\text{Ca}(\text{OH})_2$, CaCl_2 and H_2O as the initial components except Milikan (26) who started with $\text{Ca}(\text{OH})_2$, HCl and H_2O . The results of Lunge (5) and of Zahorsky (6) were rejected because their solubility values in pure water were not reliable, and because composition of the solid phase was not given. The other results are in qualitative agreement.

The solid phases present in the system as the CaCl_2 concentration increases are $\text{Ca}(\text{OH})_2$, $3\text{CaO} \cdot \text{CaCl}_2 \cdot 16\text{H}_2\text{O}$ [or $15 \text{ H}_2\text{O}$ (43)], $\text{CaO} \cdot \text{CaCl}_2 \cdot \text{H}_2\text{O}$, and $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ up to a temperature of 313 K. At temperatures above 308-313 K the phase of highest hydration disappears.

The solubility of $\text{Ca}(\text{OH})_2$ in aqueous CaCl_2 solutions decreases with increasing temperature at CaCl_2 molalities $< 0.5 \text{ mol kg}^{-1}$ (as it does in pure water), and increases with increasing temperatures at $\text{CaCl}_2 > 1 \text{ mol kg}^{-1}$. Between CaCl_2 molalities of 0.5 and 1 mol kg^{-1} there is no agreement on the temperature coefficient of solubility among the various workers. The results of O'Connor (30) are much higher than the others and are rejected.

Data for the four-component system $\text{Ca}(\text{OH})_2 + \text{CaCl}_2 + \text{NaCl} + \text{H}_2\text{O}$ have been given (60). The equilibrium solid phases are similar to those for the three-component system. They are $\text{Ca}(\text{OH})_2$, $3\text{Ca}(\text{OH})_2 \cdot \text{CaCl}_2 \cdot 12\text{H}_2\text{O}$ (or $3\text{CaO} \cdot \text{CaCl}_2 \cdot 15\text{H}_2\text{O}$), $\text{Ca}(\text{OH})_2 \cdot \text{CaCl}_2$, and NaCl .

D. $\text{Ca}(\text{OH})_2 + \text{CaX}_2 + \text{H}_2\text{O}$ X = Br or I

These systems were studied at 298 K by Milikan (25), and are analogous to the $\text{Ca}(\text{OH})_2 + \text{CaCl}_2 + \text{H}_2\text{O}$ system. The bromide-containing

<p>COMPONENTS:</p> <p>(1) Calcium hydroxide; $\text{Ca}(\text{OH})_2$; [1305-62-0]</p> <p>(2) Water; H_2O; [7732-18-5] and various aqueous solutions</p>	<p>EVALUATOR:</p> <table border="0"> <tr> <td>Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991</td><td>H. <p>CRITICAL EVALUATION:</p> <p>systems were also reported on earlier by Schreinemakers and Milikan (70). Besides $\text{Ca}(\text{OH})_2$, Milikan identified $3\text{CaO} \cdot \text{CaBr}_2 \cdot 16\text{H}_2\text{O}$, $4\text{CaO} \cdot 3\text{CaBr}_2 \cdot 16\text{H}_2\text{O}$ and $\text{CaBr}_2 \cdot 6\text{H}_2\text{O}$ as equilibrium solids in the bromide-containing system. The iodide-containing system showed regions for the three solids $\text{Ca}(\text{OH})_2$, $3\text{CaO} \cdot \text{CaI}_2 \cdot 16\text{H}_2\text{O}$ and $\text{CaI}_2 \cdot 6\text{H}_2\text{O}$.</p> <p>E. $\text{Ca}(\text{OH})_2 + \text{Ca}(\text{ClO})_2 + \text{H}_2\text{O}$</p> <p>O'Connor (30) studied this system at 273 K. He used the wet residue method to identify the solids $\text{Ca}(\text{OH})_2$, $3\text{CaO} \cdot \text{Ca}(\text{ClO})_2 \cdot 3\text{H}_2\text{O}$, $2\text{CaO} \cdot \text{Ca}(\text{ClO})_2 \cdot 2\text{H}_2\text{O}$ and $\text{Ca}(\text{ClO})_2 \cdot 3\text{H}_2\text{O}$.</p> <p>F. $\text{Ca}(\text{OH})_2 + \text{CaSO}_4 + \text{H}_2\text{O}$</p> <p>The system was investigated by Cameron and Bell (15) at 298 K. They claimed the only solid phases are $\text{Ca}(\text{OH})_2$ and $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$.</p> <p>G. $\text{Ca}(\text{OH})_2 + \text{Ca}(\text{NO}_3)_2 + \text{H}_2\text{O}$</p> <p>The system was first investigated at 298 K by Cameron and Robinson (16) who claimed the existence of solid solutions $\text{CaO} \cdot x\text{N}_2\text{O}_5 \cdot y\text{H}_2\text{O}$, a basic nitrate $2\text{CaO} \cdot \text{N}_2\text{O}_5 \cdot 1.5\text{H}_2\text{O}$ and $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$. A careful study of the same system was made by Bassett and Taylor (24) at 298 and 373 K. They found the same basic nitrate, but found no undefined solid solutions, a result which seems in better agreement with the strongly basic behavior of $\text{Ca}(\text{OH})_2$. The part of the isotherms corresponding to the equilibrium solid $\text{Ca}(\text{OH})_2$ is shown in figure 3.</p> <p>H. $\text{Ca}(\text{OH})_2 + \text{Mg}(\text{OH})_2 + \text{H}_2\text{O}$</p> <p>Bury and Davies (35) found that the presence of $\text{Mg}(\text{OH})_2$ does not influence the solubility of $\text{Ca}(\text{OH})_2$ in water, which is expected because of the low solubility of $\text{Mg}(\text{OH})_2$.</p> <p>I. $\text{Ca}(\text{OH})_2 + \text{B}_2\text{O}_3 + \text{H}_2\text{O}$</p> <p>Both Sborgi (22) and Nikolaev and Chelishcheva (39) report data on this system. The equilibrium solids reported in the two papers differ in the hydrate number. The results of Nikolaev and Chelishcheva were obtained after a much longer equilibration time, and they are considered to be the more reliable results. They reported equilibrium solids $\text{Ca}(\text{OH})_2$, $\text{CaO} \cdot \text{B}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$, $2\text{CaO} \cdot 3\text{B}_2\text{O}_3 \cdot 13\text{H}_2\text{O}$, $\text{CaO} \cdot 3\text{B}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and H_3BO_3 [or $\text{CaO} \cdot x\text{B}_2\text{O}_3 \cdot y\text{H}_2\text{O} = \text{Ca}_3(\text{BO}_3)_2 \cdot 2(3x-1)\text{H}_3\text{BO}_3 \cdot \frac{2}{3}(1-3x+y)\text{H}_2\text{O}$].</p> <p>J. $\text{Ca}(\text{OH})_2 + \text{D}_2\text{O} + \text{H}_2\text{O}$</p> <p>Kingerley and LaMer (40) measured the solubility of calcium hydroxide in mixtures of D_2O and H_2O and found by extrapolation the solubility of $\text{Ca}(\text{OD})_2$ in heavy water at 298.15 K:</p> $m_1 = 0.0112 \text{ mol kg}^{-1}$ <p><i>Five-Component Systems</i></p> <p>Hansen and Pressler (43) measured the solubility of a mixture of $\text{Ca}(\text{OH})_2$ and CaSO_4 in solutions of mixed NaOH and KOH. They do not give enough details to permit an evaluation.</p> <p>4. Ternary aqueous system containing an organic component</p> <p>A. $\text{Ca}(\text{OH})_2 + \text{C}_{12}\text{H}_{22}\text{O}_{11}$ (sucrose) + H_2O</p> <p>Data for the system $\text{Ca}(\text{OH})_2 + \text{sucrose} + \text{H}_2\text{O}$ are reported in nine publications (10, 20, 21, 32, 34, 47, 59, 61, 62) at temperatures between 288 and 353 K.</p>

<p>CRITICAL EVALUATION:</p> <p>Data from a number of these papers are rejected. Weisberg's results (10) depend on the excess of solid which indicates that equilibrium was not reached. The data are rejected. Cameron and Patten (21) and Fuchs (32) report values for the solubility of $\text{Ca}(\text{OH})_2$ in water which are too high, thus their results in the presence of sucrose were not considered. Bugaenko <i>et al.</i>'s results (59) were rejected because the sucrose concentrations were not indicated. Sapronov <i>et al.</i>'s paper (61) was rejected because it does not contain quantitative data.</p> <p>Data from the papers of Reinders and Van Gelder (34) and Koneczny <i>et al.</i> (62) show qualitative agreement. The $\text{Ca}(\text{OH})_2$ solubility increases with increasing sucrose concentration up to the formation of a sucrate compound of an undefined composition. The temperature coefficient of solubility is not apparent because of a large scatter in the experimental results. However, comparison with the data of Van Ginnekin (20) at 353 K indicates a negative temperature coefficient of solubility. Koneczny's assumption of CaO in the solid phase appears to be implausible for the aqueous solutions.</p> <p>Yokoyama (47) studied the five-component system $\text{Ca}(\text{OH})_2 + \text{NaCl} + \text{CaCl}_2 + \text{sucrose} + \text{H}_2\text{O}$. He found an increase of calcium hydroxide solubility with increasing concentration of any other solute and a decrease with increasing temperature.</p> <p>B. $\text{Ca}(\text{OH})_2 + \text{C}_3\text{H}_8\text{O}_3(\text{glycerol}) + \text{H}_2\text{O}$</p> <p>The data for this and the other ternary systems containing organic components listed below are reported in only one or two publications for each system. Thus, there is too little information to allow evaluations.</p> <p>Cameron and Patten (21) and Herz and Knoch (13) studied the glycerol-containing system at 298 K. Both observed an increase in calcium hydroxide solubility with increasing glycerol concentration up to 7 mol dm^{-3} glycerol with $\text{Ca}(\text{OH})_2$ assumed to be the equilibrium solid. The two studies are in fair agreement up to 3 mol dm^{-3} glycerol as shown in figure 4.</p> <p>C. $\text{Ca}(\text{OH})_2 + \text{C}_6\text{H}_6\text{O}(\text{phenol}) + \text{H}_2\text{O}$</p> <p>Van Meurs (27) studied this system at 298 K. He interpreted his wet residue analysis to indicate the equilibrium solids $\text{Ca}(\text{OH})_2$, $\text{Ca}(\text{C}_6\text{H}_5\text{O})_2 \cdot 3\text{H}_2\text{O}$ and $\text{C}_6\text{H}_6\text{O}$.</p> <p>D. $\text{Ca}(\text{OH})_2 + \text{CH}_3\text{O}(\text{methanol}) + \text{H}_2\text{O}$ $\text{Ca}(\text{OH})_2 + \text{C}_2\text{H}_5\text{O}(\text{ethanol}) + \text{H}_2\text{O}$</p> <p>These two systems were studied by Janković (50). The methanol-containing system was studied from 6.9 to 69.1 mass % methanol at 298 K and from 4.7 to 81.8 mass % methanol at 308 K. The ethanol-containing system was studied from 10.1 to 89.1 mass % ethanol at 298 K. In both systems the calcium hydroxide solubility decreased as the alcohol concentration increased. The solid was assumed to be $\text{Ca}(\text{OH})_2$.</p> <p>E. $\text{Ca}(\text{OH})_2 + \text{NaOH} + \text{Ca}(\text{HCOO})_2 + \text{HCHO}(\text{formaldehyde}) + \text{H}_2\text{O}$</p> <p>Belkin and Belkina (57) studied the solubility of $\text{Ca}(\text{OH})_2$ in solutions containing sodium hydroxide, calcium formate and formaldehyde. They showed that the presence of formaldehyde increases the solubility of $\text{Ca}(\text{OH})_2$ in NaOH solutions, which they attributed to the slightly acidic properties of the aldehyde in this medium.</p> <p>5. Nonaqueous binary system</p> <p>A. $\text{Ca}(\text{OH})_2 + \text{C}_5\text{H}_4\text{O}_2(\text{furfural})$</p>

CRITICAL EVALUATION:

Trimble (41) measured the solubility of $\text{Ca}(\text{OH})_2$ in anhydrous furfural at 298 K and found a solubility of about the same magnitude as that in water:

$$m_1 = 1.8 \times 10^{-2} \text{ mol kg}^{-1}.$$

6. Comparison of the present results with other evaluations.

These results are presented for comparison, and no effort has been made to judge one set of data against the other. Data were taken from three sources: Smith and Martell (64), the NBS Thermodynamic Tables (65) and the CODATA Thermodynamic Tables (69) of recommended values for some compounds of calcium.

$$\text{Ca}^{2+}(\text{aq}) + \text{OH}^{-}(\text{aq}) = \text{Ca}(\text{OH})^{+}(\text{aq})$$

Smith and Martell (64) give formation constant values at 298.15 K and two ionic strengths. At $I = 0 \text{ mol dm}^{-3}$, $\log K = 1.3 \pm 0.1$ ($K = 20$), and at $I = 3.0 \text{ mol dm}^{-3}$, $\log K = 0.64$ ($K = 4.4$).

CODATA (69) gives Gibbs energy of formation values from which one calculates the zero ionic strength value of $\log K = 1.217$ ($K = 16.5$) at 298.15 K.

$$\text{Ca}(\text{OH})_2(\text{s}) = \text{Ca}^{2+}(\text{aq}) + 2\text{OH}^{-}(\text{aq})$$

The 298.15 K zero ionic strength solubility product constant can be obtained from all three publications. The values are:

$\log K^0$	K^0	Reference
-5.19 \pm 0.2	6.5 $\times 10^{-6}$	(64)
-5.330	4.68 $\times 10^{-6}$	(65)
-5.291	5.11 $\times 10^{-6}$	(69)

The CODATA table (69) does not give a Gibbs energy of formation value for the aqueous hydroxide ion so the value from the NBS tables (65) was used.

7. Crystal structures of calcium oxide and hydroxide.

Characterization of the solid state in equilibrium with the saturated solution is an important part of any modern solubility study. The following information, mostly from the *Crystal Data Determinative Tables*, is neither complete nor evaluated, but it serves as a reminder of this important point.

It is normally stated that calcium hydroxide does not form a hydrate. However, Mellor (71) describes the work of Selivanoff who claimed to have identified a hemi-hydrate ($\text{Ca}(\text{OH})_2 \cdot 0.5\text{H}_2\text{O}$) which transformed to an amorphous form on heating. The amorphous form did not transform to the crystalline form on standing or heating in water. We are not aware that the observation was confirmed.

Crystal Formula	Type	Density, $\rho/\text{Mg m}^{-3}$
CaO ; [1305-78-8]	cubic	3.342
$\text{Ca}(\text{OH})_2$ (normal form); [1305-62-5]	hexagonal	2.244
$\text{Ca}(\text{OH})_2$ (portlandite); [12177-68-3]	hexagonal	2.23

The normal chemically pure calcium hydroxide [1305-62-8] and the mineral, portlandite [12177-68-3], differ by natural impurities.

<p>COMPONENTS:</p> <p>(1) Calcium hydroxide; $\text{Ca}(\text{OH})_2$; [1308-62-8]</p> <p>(2) Water; H_2O; [7732-18-5] and various aqueous solutions</p>	<p>EVALUATOR:</p> <p>Irma Lambert CEA/SCECF/SECA B.P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991</p> <p>H.  Claasen, H. *Z. Ver. Zuckerind.* 1911, 489.

The papers below contain information on calcium hydroxide or calcium hydroxide containing systems. The papers were rejected for various reasons including no new experimental data, not enough experimental detail to judge reliability of the data, or no solubility data when the calcium hydroxide was the stable solid phase (a number of the papers contain valid solubility data on compounds formed in the systems, but no solubility data on $\text{Ca}(\text{OH})_2$).

(a) - (c); See Source and Purity of Materials.

Results for the two highest temperatures were corrected for the dissolution of container glass.

NOTE: The unit g (kg soln.)^{-1} , used by the author.The $\text{Ca}(\text{OH})_2$ molality values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

$\text{Ca}(\text{OH})_2$ (or CaO) was equilibrated with water at the specified temperature. The resulting saturated solution was filtered, acidified with H_2SO_4 to convert the Ca^{2+} in the solution to CaSO_4 , ignited for gravimetric determination.

SOURCE AND PURITY OF MATERIALS:

(1) Calcium hydroxide. (a) White marble was dissolved in HNO_3 , and treated with $(\text{NH}_4)_2\text{CO}_3$ which precipitated CaCO_3 . The CaCO_3 was calcined to CaO , which was hydrated to $\text{Ca}(\text{OH})_2$. (b) The marble was directly calcined to CaO , which was hydrated to $\text{Ca}(\text{OH})_2$. (c) Red burned CaO was also used.

(2) Water.

ESTIMATED ERROR:

Reproducibility better than 1 %.

The molal solubilities were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A glass beaker containing $\text{Ca}(\text{OH})_2$ and distilled water was placed in a water bath. The water bath was heated or cooled to bring to the desired temperature as indicated by a thermometer in the bath. The beaker contents were filtered as soon as the desired temperature was reached. The $\text{Ca}(\text{OH})_2$ in solution was titrated by acidimetry.		(1) Calcium hydroxide. The material was considered as "perfectly free from impurities" by the author.	
		(2) Water. Distilled.	
		ESTIMATED ERROR:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The temperature is controlled by the pressure over the boiling solution. Water and excess Ca(OH) ₂ are placed in a glass container maintained at a fixed pressure by the combined use of a water pump and a constant air ingress. The solution is boiled at this pressure by placing the apparatus in a water bath at a temperature 5 to 10 degrees higher than the boiling point of the solution at the controlled pressure. After 1/2 hour of boiling, the solution is filtered by aspiration into a calibrated container located in the main vessel. Analysis is performed by drying and weighing.		Nothing specified.	
		ESTIMATED ERROR:	
		No estimates possible.

The compiler calculated the $\text{Ca}(\text{OH})_2$ concentration values.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A. CaO was slaked with a small amount of conductivity water and allowed to stand 24 h. It was then added to conductivity water at 30°C in 1 L Pyrex bottles and shaken until equilibrium reached as indicated by conductivity measurements.		(1) Calcium hydroxide. (a) Iceland spar was calcined to CaO, and hydrated to $\text{Ca}(\text{OH})_2$. (b) A chemically pure sample of CaCO_3 was dissolved in HNO_3 followed by precipitation with $(\text{NH}_4)_2\text{CO}_3$. The precipitated CaCO_3 was ignited to CaO, and hydrated to $\text{Ca}(\text{OH})_2$.	
B. The CaO was placed directly into 1 L Pyrex bottles nearly filled with conductivity water, allowed to slake and likewise was shaken until equilibrium was reached.		(2) Water. Conductivity water.	
The Ca^{2+} in the saturated solution was determined gravimetrically after precipitation as the oxalate and ignition to CaO.		ESTIMATED ERROR:	
The crystals in B. are more finely divided when conductivity measurements begin. They may initially show a higher solubility. However, time-conductivity studies show both methods come to the same solubility value in 32-36 h.		Temp.: precision ± 0.005 K. Soly.: reproducibility better than ± 0.34 %.

The $\text{Ca}(\text{OH})_2$ concentrations were calculated by the compiler.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Electrical conductivities in lime solutions of known concentration and in saturated solutions were measured with a stirring glass system under CO_2 free air in a constant temperature bath. The system was kept one hour at each temperature with periodic conductivity readings. Equilibrium was established from both increasing and decreasing temperature, and the average result was reported. The solubility was calculated by plotting the isothermal conductivity versus concentration and taking the intercept with the level corresponding to saturation.		(1) Calcium oxide. Prepared by heating Iceland spar crystals at 100°C for several days. The absence of CO_2 was tested.	
		(2) Water. Distilled. Freed from gases by repeated cycles of freezing, evacuating, and melting.	
		ESTIMATED ERROR:	
		Temp.: not stated, but given to 0.01 K in paper; Soly.: precision $\pm 0.008 \text{ g L}^{-1} \text{ CaO}$ (authors).	
Grieve, Gurd and Maas (ref 1) used the same method to obtain solubility values of 1.55, 1.45, 1.34 and 1.28 g L^{-1} at temperatures of 0, 10, 18, and 25°C, respectively. The results are considered less accurate than the present work.		REFERENCES:

EXPERIMENTAL VALUES:

An evaluation of the solubility product of $\text{Ca}(\text{OH})_2$ in water.

Solubility product values between 20 and 40 °C
by several methods

t/°C	- log K_{s0}°			
	Meth a	Meth b	Meth c	Av.
20	4.83	5.12	4.99	4.98
25	5.10	-	5.04	5.07
40	-	5.30	5.18	5.24

An evaluation was made of the solubility product of $\text{Ca}(\text{OH})_2$ from published data (ref 1 - 7). Three methods were used:

Method a. Solubility as a function of the concentration of sodium chloride solutions (ref 1 and 2). Solubility data at 20 °C (ref 1) and 25 °C (ref 2) as a function of sodium chloride concentration were analyzed by the relation

$\log m - 2A\mu^{0.5} = (1/3)\log (K_{s0}^\circ/4) - B\mu$, which had been derived from

$$K_{s0}^\circ = m_{\text{Ca}^{2+}} \cdot m_{\text{OH}^-}^2 \cdot f_{\pm}^3 \quad \text{Eqn. I}$$

where

$m_{\text{Ca}(\text{OH})_2} = m_{\text{Ca}^{2+}} - (1/2)m_{\text{OH}^-}$, and $\log f_{\pm} = 2A\mu^{0.5} - B\mu$ Eqn. II (ref 8). Here, the authors allowed m to represent either concentration or molality since the solutions were dilute, f_{\pm} is the mean activity coefficient, and μ is the ionic strength. Solubility product values at zero ionic strength are obtained.

Method b. Solubility data as a function of hydroxyl ion concentration. Solubility data at 20 and 40 °C (ref 3) as a function of KOH or NaOH concentration were analyzed graphically by the relation

$\log K_{s0}^\circ - 6A\mu^{0.5} = \log K_{s0}^\circ - 3B\mu$, which had been derived from

$K_{s0}^\circ = m_{\text{Ca}^{2+}} \cdot m_{\text{OH}^-}^2$ and Eqn. II.

Method c. Solubility as a function of temperature. All the reported solubility data (ref 1 - 7) in the range of 20 to 100 °C were plotted against temperature. The good agreement among the values indicated that the equilibrium solid was always one form of crystalline $\text{Ca}(\text{OH})_2$. The values of Bates, Bower, and Smith (ref 4) were heavily weighted, and a line was put through the data. Values from this "best" line are in the following table. The Debye-Huckel equation was used to evaluate the mean activity coefficient at each temperature. It was combined with the solubility value to obtain values of the thermodynamic solubility product at five degree intervals between 20 and 100 °C.

The solubility product values were treated by a non-linear regression to obtain the equation:

$$\ln K_{s0}^\circ = 17.67 \ln (T/K) - 0.078(T/K) - 89.0$$

It was pointed out by the authors that the coexistence of CaOH^+ , the purity of the starting $\text{Ca}(\text{OH})_2$ samples, and the crystallinity of $\text{Ca}(\text{OH})_2$ did not influence the solubility data, and that only one form of crystalline $\text{Ca}(\text{OH})_2$ was present in equilibrium with its saturated solutions.

AUXILIARY INFORMATION																																										
METHOD/APPARATUS/PROCEDURE: Isothermal Method. Slaked lime containing about 20 mass % Ca(OH) ₂ was prepared from CaO and distilled water. Mixtures containing initially either 1.5 or 3.0 mass % Ca(OH) ₂ were equilibrated by mixing at 0°C for 30 minutes. Samples of the suspension were taken for analysis immediately after preparing the mixture, and then at 7, 15 and 30 minute intervals. The samples were filtered at 0°C through a sintered glass crucible (S2). The filtration took approximately 1 minute. Two aliquots of the filtrate were analyzed, one for Ca ²⁺ by complexometric titration, and the other for Ca(OH) ₂ by titration with standard 0.1 mol L ⁻¹ HCl.	SOURCE AND PURITY OF MATERIALS: (1) Calcium oxide. Lachema, Brno, Czechoslovakia. Analyzed titrimetrically and contained 96.3 mass % CaO. ESTIMATED ERROR: No estimates possible. COMPONENTS:		ORIGINAL MEASUREMENTS:			
(1) Calcium hydroxide (portlandite); Ca(OH) ₂ ; [12177-68-3]		Walther, J. V.			
(2) Water; H ₂ O; [7732-18-5]		Geochim. Cosmochim. Acta 1986, 50, 733-39.			
VARIABLES:		PREPARED BY:			
T/K = 573 - 877 p/MPa = 99.0 - 302.0		H. L. Clever			
EXPERIMENTAL VALUES:					
The solubility of portlandite in super-critical water as a function of temperature and pressure.					
Temperature		Pressure	Duration	Approach	log (m _{Ca} /mol kg ⁻¹)
t/°C	T/K	p _{tot} /bar	t/days		
503	776	3000	3	U	-2.657
		3000	2	-	-2.627
600	873	3000	1	U	-3.998
603	876	3020	1	S	-3.099
604	877	3020	2	U	-3.090
Approach: S from supersaturation, U from undersaturation, and - from near same concentration (within 10%).					
The author's data in the paper were arranged in the order the experiments were done on the 2 g sample of Ca(OH) ₂ . The compiler arranged the data above in the order of increasing temperature at the pressures of 1, 1.5, 2, 2.5 and 3 kbar.					
The author proposes the solubility reaction		although the solution pH is about 2 units above neutral. The solubility increases with increasing pressure at constant temperature, decreases with increasing temperature at constant pressure.			
2H ⁺ (aq) + Ca(OH) ₂ (s) = Ca ²⁺ (aq) + 2H ₂ O					
Neither Ca(OH) ⁺ (aq) or Ca(OH) ₂ (aq) appear to be important species,					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:			
The solubility measurements were performed with an extraction quench hydrothermal apparatus (ref 1). A 2 g sample of Ca(OH) ₂ was defloculated and the fines removed by settling. X-ray and optical microscope examination indicated a completely crystalline material.		(1) Portlandite. Sargent Welch reagent grade. Treated as described in the method.			
The sample was brought to its first sampling temperature and pressure and allowed to equilibrate for seven days. Successive measurements followed at 1 to 10 (usually 2 to 4) day intervals. After sampling the sampling apparatus was flushed with an NaOH soln. The calcium concentration was determined using a DCP plasma spectrometer.		(2) Water. Distilled, deionized, and decarbonated.			
		ESTIMATED ERROR:			
		Author estimated analytical method for Ca as ±2 %, over-all with uncertainties in p and T as ±5 %.

* Solid contained some calcium oxychloride. The compiler calculated the $\text{Ca}(\text{OH})_2$ concentrations. At 20°C the CaCl_2 concentrations are 0, 0.468, 0.976, 1.53, 2.12, 2.77 and 3.46 mol L^{-1} .			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The paper is concerned mostly with the properties and composition of calcium oxychloride. Only limited details about the solubility measurement. The $\text{Ca}(\text{OH})_2$ soly values in pure water appear high.		Nothing specified.	
		ESTIMATED ERROR:	
		No estimates possible.	

COMPONENTS:		ORIGINAL MEASUREMENTS:	
(1) Calcium hydroxide; $\text{Ca}(\text{OH})_2$; [1305-62-0]		Schreinemakers, F.A.H.; Figuee, Th.	
(2) Calcium chloride; CaCl_2 ; [10043-52-4]		<i>Chem. Weekbl.</i> <u>1911</u> , 36, 683-88.	
(3) Water; H_2O ; [7732-18-5]			
VARIABLES:		PREPARED BY:	
$T/\text{K} = 298$ Composition		I. Lambert

Solid Phases: A. $\text{Ca}(\text{OH})_2$ B. $\text{CaCl}_2 \cdot 4\text{CaO} \cdot 14\text{H}_2\text{O}$			
C. $\text{CaCl}_2 \cdot \text{CaO} \cdot 2\text{H}_2\text{O}$ D. $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$			
In the author's notation D_{14}^4 , D_2^1 , and Ca_6 are B, C and D, respectively.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The saturated solutions are analyzed for CaCl_2 by titration with $0.1 \text{ mol L}^{-1} \text{AgNO}_3$, and for CaO by titration with $0.1 \text{ mol L}^{-1} \text{HCl}$. The wet residue is dissolved in a sucrose solution and analyzed as above. The solid phase composition is calculated by the "method of residues".		Nothing specified.	
		ESTIMATED ERROR:	
		No estimates possible.

Solid Phases: A $\text{Ca}(\text{OH})_2$; B $\text{CaCl}_2 \cdot 3\text{CaO} \cdot 16\text{H}_2\text{O}$; C $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$				
The $\text{Ca}(\text{OH})_2$ mass percents were calculated by the compiler.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
Ca(OH) ₂ and CaCl ₂ were equilibrated with water at 0°C for 24 h. Samples of the saturated solution were analyzed for Ca(OH) ₂ by neutralization titration, and for CaCl ₂ by titration of the chloride ion by the Volhard method.		(1) Calcium hydroxide. Freshly calcined CaO was slaked.		
		Nothing further specified.		
		ESTIMATED ERROR:		
		No estimates possible.

Aliquots of the saturated aqueous phases were analyzed for Cl ⁻ by titration with standard Hg ²⁺ solution using sodium nitroprusside indicator, for Ca ²⁺ by titration with standard EDTA solution using a mixed indicator (not specified in the text), for OH ⁻ by titration with standard HCl solution using methyl red indicator, and for Na ⁺ by flame photometry. No other experimental details are given.		Nothing specified.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
Ca(OH) ₂ and Ca(ClO) ₂ were equilibrated with water at 0°C for 1-5 days. Samples of the saturated solution were analyzed for Ca(OH) ₂ by neutralization titration after decomposition of the ClO ⁻ by hydrogen peroxide, and for Ca(ClO) ₂ by an iodometric titration.		(1) Calcium hydroxide. Freshly calcined CaO was slaked.		
		(2) Calcium hypochlorite. Prepared by the reaction of aqueous Ca(OH) ₂ with Cl ₂ gas, and recrystallization from water. The purified salt contained no Cl ₂ or Ca(ClO ₃) ₂ , but contained 0.5 wt % Ca(OH) ₂ .		
		Nothing further specified.		
		ESTIMATED ERROR:		
		No estimates possible.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The components were placed in a glass vessel, thermostated at 15°C, and stirred 48 to 72 hours to establish equilibrium.		(1) Calcium oxide, CaO. A 96 % base was obtained by heating commercial oxide.	
The liquid and solid residues were analyzed for bromide by iodometry, and for calcium by complexometric titration with Trilon B.		(2) Calcium bromide. Pure chemical grade, recrystallized twice.	
The solid phase composition was determined by Schreinemakers' method of residues. The crystals were examined by microscopy.		(3) Water. Distilled.	
		ESTIMATED ERROR:	
		No estimates possible.

<p>EXPERIMENTAL VALUES:</p> <p>The solid phase is always $\text{Ca}(\text{OH})_2 + \text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ except for the rows marked "x" where probably $\text{CaSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ formed.</p> <p>Many of the data are shown in the figure to the right. The solubilities of $\text{Ca}(\text{OH})_2$ and CaSO_4 are about the same in $\text{K}_2\text{O} + \text{Na}_2\text{O}$ as in K_2O alone. They differ slightly in Na_2O from the values in the two alkalis or K_2O alone. From two to four values were obtained at one concentration of $\text{K}_2\text{O} + \text{Na}_2\text{O}$, but when they differed so little that it did not show on the scale of the figure only the average value was plotted.</p>	 <p>Legend: • Data for Solutions of KOH x " " " " " NaOH • " " " " " KOH & NaOH</p> <p>Y-axis (top): Moles SO_3 per liter at 30°C Y-axis (bottom): Moles CaO X-axis: Moles K_2O and Na_2O per liter Caption: Concentrations of CaO and SO_3 vs. Concentrations of K_2O and Na_2O</p>
AUXILIARY INFORMATION	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>An excess of finely powdered CaO and gypsum were added to standardized solutions of alkali hydroxides. The reaction mixtures were agitated in Erlenmeyer flasks in a thermostated water bath for 48 hours. The saturated solutions were filtered with care to protect from air. Samples were taken from the filtrate. The total alkalinity was determined by acidimetry. The CaO was determined by precipitation of the oxalate and titration with standard KMnO_4. The SO_3 was precipitated and weighed as BaSO_4. The Na_2O was precipitated and weighed as sodium uranyl zinc acetate.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Nothing specified.</p> <p>ESTIMATED ERROR:</p> <p>Temp.: $\pm 0.1^\circ\text{C}$ (precision) Soly.: No estimates possible.</p> <p>REFERENCES:</p>

Solid Phases:

A $\text{Ca}(\text{OH})_2$ B $\text{CaO} \cdot x\text{N}_2\text{O}_5 \cdot y\text{H}_2\text{O}$ (solid solution)C $\text{CaO} \cdot \text{Ca}(\text{NO}_3)_2 \cdot 3.5\text{H}_2\text{O}$ (hydrated basic calcium nitrate)D $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$

The authors also tabulate g/100 g water of both calcium nitrate and calcium oxide as calcium hydroxide.

The numbers in columns two and four above were calculated by the compilers.

<p>COMPONENTS:</p> <p>(1) Calcium hydroxide; $\text{Ca}(\text{OH})_2$; [1305-62-0]</p> <p>(2) Calcium nitrate; $\text{Ca}(\text{NO}_3)_2$; [10124-37-5]</p> <p>(3) Water; H_2O; [7732-18-5]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Cameron, F. K.; Robinson, W. O.</p> <p><i>J. Phys. Chem.</i> <u>1907</u>, 11, 273-8.</p>
<p>VARIABLES:</p> <p>$T/K = 298$</p> <p>$\text{Ca}(\text{NO}_3)_2/\text{mass } \% = 3.27 - 57.74$</p>	<p>PREPARED BY:</p> <p>H. Einaga</p> <p>I. Lambert</p>
<p>EXPERIMENTAL VALUES:</p> <div style="display: flex; justify-content: space-around; align-items: flex-start;">   </div> <p>The authors carried out a wet residue analysis from which they constructed the figures above. The right figure shows regions of stability for pure calcium hydroxide, a solid solution, and a hydrated basic calcium nitrate. The region for pure $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ is not shown. The solubility curve to the left shows all regions with the equilibrium solid identified above each branch.</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Freshly prepared CaO was added in excess to aqueous $\text{Ca}(\text{NO}_3)_2$ solutions of known concentration. The mixtures were equilibrated at 25°C by mixing for more than six weeks. An aliquot of saturated solution was titrated with standard HNO_3 solution with phenolphthalein indicator to determine the dissolved $\text{Ca}(\text{NO}_3)_2$.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <ol style="list-style-type: none"> (1) Calcium oxide. Freshly prepared lime. (2) Calcium nitrate. Calcium carbonate impurity converted to the nitrate by treatment with nitric acid. (3) Water. Freshly boiled distilled water. <p>ESTIMATED ERROR:</p> <p>No estimate possible.</p> <p>REFERENCES:</p>

The solid phase in equilibrium with the saturated solution was Ca(OH) ₂ . The solubility of Ca(OH) ₂ in aqueous LiOH solution had a negative temperature coefficient between 25 and 100°C.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
CaO was equilibrated with aqueous LiOH in a Fluoroplast vessel with a hydraulic seal at specified temperature within ± 0.1 °C. The samples were stirred 10 h at 100°C and 48 h at 25°C. After saturation, Li ⁺ in the solution was determined by flame photometry, and Ca ²⁺ by complexometry with EDTA using fluorexone as an indicator and by flame photometry.		(1) Calcium oxide. Prepared by heating high purity CaCO ₃ .	
The complexometric titration could not be used for samples high in Li ₂ O.		(2) Lithium hydroxide. Chemically pure LiOH·H ₂ O was used.	
		(3) Water.	
		ESTIMATED ERROR:	
		Relative error for the determination of Ca ²⁺ was 5.5 % at 0.005 mass %, 10 % at 0.002 mass %, 30 % at 0.001 mass % and +24 to -42 % at < 0.001 mass %.	
		Temp.: accuracy ± 0.1 K (authors).

The experimental data in columns 1 and 2 are from (ref 1).					
The author calculated the concentrations of Ca^{2+} , CaOH^+ , and OH^- ions from his study of the dissociation of $\text{Ca}(\text{OH})_2$. He measured the solubility of $\text{Ca}(\text{IO}_3)_2$ in solutions of NaOH and $\text{Ca}(\text{OH})_2$. By assuming that the small amount of IO_3^- dissolved is entirely ionized the dissociation of $\text{Ca}(\text{OH})_2$ can be computed. See <i>Solubility Series</i> <u>1983</u> , 14, 99 and 102.					
The thermodynamic solubility product, $K_{s0}^\circ = 5.47 \times 10^{-6}$, was calculated from K_{s0} values using activity coefficients of $\text{Ca}(\text{OH})_2$, Ca^{2+} , CaOH^+ , and OH^- (ref 2). The activity coefficient relations used were:					
$\log f_{\text{Ca}^{2+}} - 3 \log f_{\text{Ca}(\text{OH})_2} - 2 \log f_{\text{OH}^-},$					
$\log f_{\text{CaOH}^+} = -0.50 I^{0.5} + 0.1 I, \text{ and}$					
$\log f_{\text{Ca}(\text{OH})_2} = -1.008 I^{0.5} + 0.90 I, \text{ where } I \text{ is ionic strength.}$					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
The author's experiment was the determination of the solubility of $\text{Ca}(\text{IO}_3)_2$ in the presence of NaCl and NaOH or NaCl and $\text{Ca}(\text{OH})_2$. From his experiment he calculated the dissociation of $\text{Ca}(\text{OH})_2$ which he then applied to the solubility data of Johnston and Grove (ref 1) to obtain the $\text{Ca}(\text{OH})_2$ solubility product as described above.			See paper (ref 1) and data sheet in this volume of Johnston and Grove.

The solubility product of Ca(OH) ₂ , K _{s0} [°] = a _{Ca²⁺} · a _{OH⁻} ² , was calculated from the measured concentration of Ca(OH) ₂ and the hydrogen ion activity, a _{H⁺} , by considering the following equilibria: 2H ₂ O = H ₃ O ⁺ + OH ⁻ ; Ca ²⁺ + H ₂ O = CaOH ⁺ + H ₃ O ⁺ ; Ca(OH) ₂ (s) = Ca ²⁺ + 2OH ⁻ . From the relations, [Ca(OH) ₂] = [Ca ²⁺] + [CaOH ⁺] and 2[Ca ²⁺] + [CaOH ⁺] = [OH ⁻], and using the activity coefficients of Ca ²⁺ and OH ⁻ calculated from the Debye-Huckel equation, log K _{s0} [°] = -5.22 ± 0.02.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Ca(OH) ₂ was equilibrated with aqueous NaCl solution at 25.0 ± 0.1°C by shaking for 2 h. The saturated aqueous phase was filtered, and the dissolved Ca(OH) ₂ was determined by titration with standard HCl solution using phenolphthalein indicator. All procedures were carried out under a nitrogen atmosphere. The pH of the saturated solution was determined potentiometrically using a hydrogen electrode.		(1) Calcium hydroxide. Prepared from reagent grade CaO. The CaO was calcinated 1 h at 1000-1100°C, and the product slaked in a Soxhlet apparatus. The Ca(OH) ₂ formed was dried in a N ₂ atmosphere. (2) Sodium chloride. Reagent grade. (3) Water. CO ₂ free conductivity water (<2 × 10 ⁻⁶ Ω ⁻¹).	
		ESTIMATED ERROR: No estimates possible.

AUXILIARY INFORMATION																			
METHOD/APPARATUS/PROCEDURE: Well-defined crystals of $\text{Ca}(\text{OH})_2$ were equilibrated at $25 \pm 0.02^\circ\text{C}$ for 24 hours with aqueous sodium bromide solutions and protected from atmospheric CO_2 . $\text{Ca}(\text{OH})_2$ in the saturated solutions was determined by titration with standard HCl solution using phenolphthalein and/or methyl red as indicators, and NaBr was determined titrimetrically by the Mohr method.	SOURCE AND PURITY OF MATERIALS: (1) Calcium hydroxide. Crystalline form (hexagonal pyramids) of highest purity was prepared by the mutual diffusion process of CaCl_2 and NaOH in aqueous solution free of CO_2 . Its purity was 99.92% but contained 0.075% (as NaCl) or 0.071% (as CaCl_2) impurity. (2) Sodium bromide. Chemically pure grade used after several recrystallizations from distilled water. (3) Water. COMPONENTS: (1) Calcium hydroxide; $\text{Ca}(\text{OH})_2$; [1305-62-0] (2) Sodium nitrate; NaNO_3 ; [7631-99-4] (3) Water; H_2O ; [7732-18-5]	ORIGINAL MEASUREMENTS: Yeatts, L. B.; Marshall, W. L. <i>J. Phys. Chem.</i> 1967 , 71, 2641-50.
VARIABLES: $T/\text{K} = 273 - 623$ $m_2/\text{mol kg}^{-1} = 0 - 6.29$	PREPARED BY: H. Einaga Y. Komatsu I. Lambert
EXPERIMENTAL VALUES: <p>The solubility product, $K_{\text{S}0}^*$, was calculated from experimental data according to the following relation (equation I):</p> $K_{\text{S}0}^* = \log K_{\text{S}0} + 3 \log \gamma_{\pm}$ $\log \gamma_{\pm} = -2S\mu^{1/2}/(1 + A\mu^{1/2}) - B\mu - C\mu^2$ <p>is the extended Debye-Huckel equation. $K_{\text{S}0}^*$ is the stoichiometric solubility product at the ionic strength μ (in molal units), γ_{\pm} signifies a mean activity coefficient of Ca^{2+} and OH^-, S is the limiting Debye-Huckel slope for a 1:1 electrolyte, and A, B, and C are empirically derived constants.</p> <p>The following relation (equation II) was deduced experimentally,</p> $\log K_{\text{S}0}^* = -25.7085 + 12.9722 \log(T/\text{K}) - 530.49/(T/\text{K}) - 0.0323310(T/\text{K}).$	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: <p>For the two lower temperatures solid $\text{Ca}(\text{OH})_2$ was equilibrated with aqueous NaNO_3 solution in Kel F 800 coated pyrex bottles at the desired temperature for 2 to 5 hours. At the higher temperatures special high pressure vessels were used (ref 1) and equilibration time was 22-64 hours. The resulting solutions were analyzed for Ca^{2+} by complexometry and for $\text{NaNO}_3 + \text{Ca}(\text{OH})_2$ by gravimetry after neutralization with HNO_3 and evaporation to dryness.</p>	SOURCE AND PURITY OF MATERIALS: (1) Calcium hydroxide. Reagent grade; in the 0.5 and 25°C experiments, the $\text{Ca}(\text{OH})_2$ used was predigested at 250° for four hours. (2) Sodium nitrate. Reagent grade. (3) Water.
ESTIMATED ERROR: The estimated error in the solubility data was calculated by the compilers to be less than 2% below 150°C; above this, it increased with temperature to 6% at 350°.

AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE:	SOURCE AND PURITY OF MATERIALS:
Calcium oxide was equilibrated with aqueous KOH solution at a specified temperature by agitation. The resulting saturated solutions were filtered, and the filtrate was analyzed for hydroxide ion by titration with standard HCl solution, and for calcium ion by titration with standard permanganate solution after its separation as the oxalate. The filtration and analytical procedures were carried out in the absence of atmospheric carbon dioxide.	(1) Calcium oxide. Analytical grade CaO was digested four days in boiling distilled water in order to obtain large crystals (ref 1). (2) Potassium hydroxide. Nothing specified. (3) Water. Distilled.
	ESTIMATED ERROR:
	No estimate possible.

The solubility product of Ca(OH) ₂ , K _{s0} [°] = a _{Ca²⁺} · a _{OH⁻} ⁻² , was calculated from the measured concentration of Ca(OH) ₂ and the hydrogen ion activity, a _{H⁺} , by considering the following equilibria:			
2H ₂ O = H ₃ O ⁺ + OH ⁻ ; Ca ²⁺ + H ₂ O = CaOH ⁺ + H ₃ O ⁺ ; Ca(OH) ₂ (s) = Ca ²⁺ + 2OH ⁻ .			
From the relations, [Ca(OH) ₂] = [Ca ²⁺] + [CaOH ⁺] and 2[Ca ²⁺] + [CaOH ⁺] = [OH ⁻], and using the activity coefficients of Ca ²⁺ and OH ⁻ calculated from the Debye-Huckel equation, log K _{s0} [°] = -5.35 ± 0.01.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Ca(OH) ₂ was equilibrated with aqueous KCl solution at 25.0 ± 0.1°C by shaking for 2 h. The saturated aqueous phase was filtered, and the dissolved Ca(OH) ₂ was determined by titration with standard HCl solution using phenolphthalein indicator. All procedures were carried out under a nitrogen atmosphere. The pH of the saturated solution was determined potentiometrically using a hydrogen electrode.		(1) Calcium hydroxide. Prepared from reagent grade CaO. The CaO was calcinated 1 h at 1000-1100°C, and the product slaked in a Soxhlet apparatus. The Ca(OH) ₂ formed was dried in a N ₂ atmosphere.	
		(2) Potassium chloride. Reagent grade.	
		(3) Water. CO ₂ free conductivity water (<2 x 10 ⁻⁶ Ω ⁻¹).	
		ESTIMATED ERROR:	
		No estimates possible.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
An aqueous solution of calcium formate, formaldehyde, and sodium hydroxide was equilibrated with excess calcium hydroxide for 10-15 minutes at $25 \pm 0.5^\circ\text{C}$. Samples of the resulting saturated solution were analyzed for calcium ion by a gravimetric method, for calcium hydroxide by a neutralization titration method, and for the formaldehyde by using hydroxylamine. The pH of the solution was measured with a glass electrode.		(1) Calcium hydroxide. Analytical grade.	
		(2) Sodium hydroxide. Chemically pure.	
		(3) Calcium formate. Chemically pure.	
		(4) Formaldehyde. Freshly distilled, free of methanol.

Attempts to determine the nature of the solid by the wet residue method failed due to the high solution viscosity which prevented satisfactory separation of mother liquid and solid. The authors state the solid is either $\text{Ca}(\text{OH})_2$ or a series of solid solutions containing $\text{Ca}(\text{OH})_2$.			
The solubility of $\text{Ca}(\text{OH})_2$ in water is from Cameron and Bell (ref 1).			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Cane sugar solutions varying from 0.5 to 40 mass % were prepared, and slaked lime added to each in slight excess. These were brought to equilibrium at about 0°C, the supernatant liquid poured off, and the saturated liquid thermostated at 25°C where the solubility is less. A finely divided solid forms which shows no tendency to aggregate.		Nothing specified.	
The sucrose in the saturated solution was determined by weighing the CO_2 formed by dry combustion of the solution. The $\text{Ca}(\text{OH})_2$ was determined by evaporation of the solution, burning off the sucrose, and igniting to CaO .		ESTIMATED ERROR:	
		No estimates possible.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
A solution of 5 g of Ca(OH) ₂ in 10 g of water, and a solution of sucrose of the desired concentration are heated separately at 80°C in a thermostat. When temperature equilibrium is established the solutions are mixed with care to see that no cooling occurs. The resulting solution was shaken several hours in the thermostat. The time necessary for equilibrium was checked by performing experiments of 4, 8, and 24 hours shaking time. After 8 hours no change in composition occurred.		Nothing specified.	
Samples were filtered through a cotton wool plug, and analyzed for Ca(OH) ₂ by acidimetry with phenolphthalein as indicator, and for sucrose by polarimetry.		ESTIMATED ERROR:

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Aqueous sucrose solutions of known concentration were mixed with stoichiometric amounts of NaOH and CaCl_2 solutions. The freshly precipitated $\text{Ca}(\text{OH})_2$ was equilibrated with the solution at 17.0-17.5 °C with frequent five minute periods of shaking. The excess solid $\text{Ca}(\text{OH})_2$ was filtered off, and the filtrate titrated with standard HCl solution using methyl orange indicator to determine the dissolved $\text{Ca}(\text{OH})_2$. The concentration of NaCl in the solutions is unknown.		No description, but analytical reagent grade CaCl_2 and NaOH were probably used.	
		ESTIMATED ERROR:	
		Temp: range given as 17.0 to 17.5 °C.	
		Soly.: No estimates possible.

CRITICAL EVALUATION:

An evaluation of the solubility of strontium hydroxide in water and various aqueous solutions.

Quantitative measurements of the solubility of strontium hydroxide, $\text{Sr}(\text{OH})_2$, in aqueous solutions have been reported in 13 rather old papers. Many of these papers are related to the use of strontium hydroxide in refining sugar from sugar beets. The solubility of strontium hydroxide in pure water is reported in six papers (1, 2, 9-12). The SrO + sucrose + water system is described (9-12). Phase diagrams of the systems SrO + strontium salts (SrCl_2 , SrBr_2 , SrI_2 , $\text{Sr}(\text{NO}_3)_2$ and $\text{Sr}(\text{SH})_2$) + H_2O were also determined (3, 5, 6, 8). A review of early solubility work in Mellor (18) contains some references not covered here.

1. The solubility of strontium hydroxide in water.

Different investigators all measured the solubility of strontium hydroxide in water by a similar method, involving isothermal equilibration of $\text{Sr}(\text{OH})_2$ or SrO with water, filtration and acidimetric titration. The source and purity of the $\text{Sr}(\text{OH})_2$ or SrO were not given. In spite of the probable different origin of the strontium compounds, the reported results (1, 2, 9-12) are in good agreement up to a temperature of 343 K, but diverge at higher temperatures. All the solubility values are shown in Figure 1. The solubility increases with temperature. Above 358 K only Reinders and Klinkenberg (11) found a decrease of solubility with increasing temperature.

All of the authors identify the solid phase in equilibrium with the saturated solution as $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ at the lower temperatures. Reinders and Klinkenberg (11) claim that the stable phase above 358 K is $\text{Sr}(\text{OH})_2 \cdot \text{H}_2\text{O}$, which should have a different solubility and temperature coefficient of solubility, as they observed. The observed increase in solubility above 358 K (2, 9, 10; Fig. 1) may be related to the existence of a metastable octahydrate.

The data were fitted by the method of least squares to a type of equation recommended in the "Introduction to the Solubility of Solids in Liquids", eqn [48], with activity and osmotic coefficient terms included in the Y_m function. This equation is based on a thermodynamic treatment of saturated solutions and their equilibrated solid phases and has the form

$$Y_m = A_1 + A_2/(T/K) + A_3 \ln (T/K).$$

where $Y_m = \ln (m/m_0) - (m/m_0 - 1)$ with $1/m_0 = 0.144 \text{ kg mol}^{-1}$ at the congruent fusion temperature, T_c . When the usual procedure of discarding points which deviate by more than two standard deviations and repeating the fit was applied, the points noted in Table 1 were discarded.

The resulting fitting equation is:

$$Y_m = -231.074 + 7392.013/(T/K) + 35.5946 \ln (T/K) \quad [1]$$

with $\sigma(Y_m) = 0.033$. The standard deviation in molality and the congruent octahydrate melting point are $\sigma(m) = 0.027$ and $T_m = 384.3 \text{ K}$ with $\sigma(T_m) = 0.4 \text{ K}$.

The equation was used to calculate the recommended solubility values at 5 degree intervals from 273.15 to 373.15 K in Table 2 and the fitted curve in Figure 1.

CRITICAL EVALUATION:

Figure 1. The solubility of strontium hydroxide as a function of temperature. Experimental points from Table 1 with fitted equation calculated from Eqn [1] assuming metastable octahydrate, $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}(\text{s})$.

COMPONENTS:	EVALUATOR:
(1) Strontium hydroxide; $\text{Sr}(\text{OH})_2$; [18480-07-4]	Irma Lambert CEA/SCECF/SECA B. P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5], and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

The recommended values come from the treatment of data up to 374 K corresponding to a metastable octahydrate.

2. Ternary systems $\text{SrO} + \text{SrX}_2 + \text{H}_2\text{O}$.

Milikan (5, 6) studied the ternary systems $\text{SrO} + \text{SrX}_2 + \text{H}_2\text{O}$ with $\text{X} = \text{Cl}^-$, Br^- and I^- at temperatures near 298 K. He showed the formation of hydrated compounds in all three cases. They were $\text{SrCl}_2 \cdot \text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ (or $\text{SrCl}_2 \cdot \text{SrO} \cdot 9\text{H}_2\text{O}$), $\text{SrBr}_2 \cdot \text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ (or $\text{SrBr}_2 \cdot \text{SrO} \cdot 9\text{H}_2\text{O}$), and $\text{SrI}_2 \cdot \text{Sr}(\text{OH})_2 \cdot 7\text{H}_2\text{O}$ (or $\text{SrI}_2 \cdot \text{SrO} \cdot 8\text{H}_2\text{O}$), respectively. The first system was studied over the 273 to 313 K temperature range, and the solid $\text{SrCl}_2 \cdot \text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ appeared only at temperatures equal to or higher than 298 K.

The $\text{SrO} + \text{Sr}(\text{NO}_3)_2 + \text{H}_2\text{O}$ system was studied by Parson and Perkins (3), and the $\text{SrO} + \text{Sr}(\text{SH})_2 + \text{H}_2\text{O}$ system was studied by Terres and Brückner (8). Mixed compound formation was not observed in either of these systems. It was observed in the $\text{Sr}(\text{OH})_2 + \text{Sr}(\text{NO}_3)_2 + \text{H}_2\text{O}$ system (14).

3. Strontium oxide + sucrose + water systems.

Data for the sucrose-containing ternary systems are reported in four publications (9-12). Qualitative agreement exists concerning the solid phases possibly in equilibrium with the solution. They are $\text{SrO} \cdot 9\text{H}_2\text{O}$ (or $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$), $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot 2\text{SrO}$ and $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot \text{SrO}$. The later two substances result from reaction of $\text{Sr}(\text{OH})_2$ with the two $-\text{CH}_2\text{OH}$ groups in sucrose:

with $x = 1, 2$.

Solubility isotherms obtained by different authors were compared when a common range of temperature and sucrose concentration was available. We compared results from (10) and (11) at 298.15 and 363.15 K, and from (10) and (12) at 348.15 K. No agreement, even as to the shape of the isotherms, exists between the pairs of data sets compared. The results reported by Reinders and Klinkenberg (11) at 343.15 K were compared to the data of Nischizawa and Hachihama (12) at 348.15 K and they were found to be compatible.

Reinders and Klinkenberg observed that equilibrium was very difficult to reach, especially at high sucrose concentration, when the viscosity of the solution increases. A gel may be obtained when the sucrose concentration reaches 20 mass %. Metastable equilibria were also observed. The time necessary to reach equilibrium was not recorded for each set of data, but the authors mention times of 3 to 9 days at 298.15 K. Grube and Nussbaum (10) do not mention a time of equilibration for their experiments. Siderski (9) took samples after some hours. The data of these two publications (9, 10) were rejected because of insufficient time of equilibration.

As indicated above, data from (11) and (12) are in qualitative agreement at the relatively close temperatures of 343.15 and 348.15 K in the common sucrose concentration range (mass fraction < 0.3) as to both solubility values and solid phases, which are $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ and $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot 2\text{SrO}$. Their data may be considered as "tentative". Reinders and Klinkenberg (11) determined the range of stability of the different solids at other temperatures. They found the solid $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot \text{SrO}$ (monosucchrate) was stable at temperatures lower than 343 K. At higher temperatures the stable solid is the disucchrate.

4. The solubility of strontium hydroxide in mixed solvents.

Rothmund (4) compared the effect of the addition of different organic substances at a concentration of 0.5 mol dm^{-3} on the solubility of

COMPONENTS:	EVALUATOR:
(1) Strontium hydroxide; $\text{Sr}(\text{OH})_2$; [18480-07-4]	Irma Lambert CEA/SCECF/SECA B. P. 6 92265 Fontenay- aux-Roses Cedex FRANCE November, 1991
(2) Water; H_2O ; [7732-18-5], and various aqueous solutions	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

$\text{Sr}(\text{OH})_2$ in water. Some alcohols (mannitol, propanetriol and ethanediol) enhance the solubility. Van Meurs (7) observed an enhancement of the solubility in the SrO + phenol + water system, and he showed the existence of the solid compound $\text{Sr}(\text{C}_6\text{H}_5\text{O})_2 \cdot 4\text{H}_2\text{O}$.

The SrO + ethanol + water system was studied at 298 K by Janković (13). He claimed that the only solid phase is $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$.

As there are no confirmatory data for these systems, these data are classed as tentative.

5. Results from other evaluations.

Smith and Martell (15) give the association constant at 298.15 K and ionic strengths of 0 and 3.0 mol dm^{-3} for $\text{Sr}^{2+}(\text{aq}) + \text{OH}^{-}(\text{aq}) = (\text{SrOH})^{+}(\text{aq})$ as:

Ionic Strength mol dm^{-3}	$\log K$	K
0	0.8 ± 0.1	6.3
3.0	0.23	1.7

The *NBS Thermodynamic Tables* (16) do not have values of the Gibbs energy of formation for any solid forms of strontium hydroxide, and no calculations can be made regarding the solid. There are data to calculate the association constant above. At 298.15 K and zero ionic strength the value is $K = 1.0$.

6. Crystal structure of strontium hydroxide.

Characterization of the solid state in equilibrium with the saturated solution is an important part of any modern solubility study. The following information, mostly from the *Crystal Determinative Tables* (17), is neither complete nor evaluated, but it serves as a reminder of this important point.

Crystal Formula	Type	Density, $\rho/\text{Mg m}^{-3}$
SrO ; [1314-11-0]	Cubic	5.235
$\text{Sr}(\text{OH})_2$; [18480-07-4]	Orthorhombic	3.407
$\text{Sr}(\text{OH})_2 \cdot \text{H}_2\text{O}$; [21800-33-9]	Orthorhombic	3.07
$\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$; [1311-10-0]	Tetragonal	1.88

17. Donnay, J.D.H.; Ondik, H.M., Editors, *CRYSTAL DATA DETERMINATIVE TABLES*, Published jointly by the National Bureau of Standards and the Joint Committee on Powder Diffraction Standards, 1973, Volume 2.
18. Mellor, J. W. *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*, Longmans, Green and Co., London, 1923, pp. 673-87.

Mellor lists and discusses several papers on the solubility of strontium hydroxide not included in this volume. We believe the papers listed below can be rejected because of one or more of the following reasons, impure materials, presence of atmospheric carbon dioxide, and insufficient time allowed to reach equilibrium.

Bucholz, C. F. *Gehlen's J.* 1807, 4, 128.
Bineau, A. *C. R. Hebd. Seances Acad. Sci.* 1855, 41, 509.

The following paper listed by Mellor contains a discussion of the relative order of solubility among the alkaline earth hydroxides.

Tilden, W. A. *Proc. Roy. Soc.* 1886, 38, 401.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Sr(OH) ₂ and water are placed in a stoppered flask fitted with two tubes passing through the cork, one of them with a felt plug at the end. After some hours at the desired temperature, samples are withdrawn by forcing the solution through the felt plug and then the Sr(OH) ₂ concentration is analyzed by acidimetry. Temperatures are controlled by an ice bath (0°C), by flowing water (11 - 13°C), by a thermostated bath (40 - 90°C), and by boiling (101°C). 20 - 24°C are the ambient temperatures. Each experiment is repeated two or three times.		(1) Strontium hydroxide. Prepared from "Strontionite" (SrCO ₃ ore) ignited, dissolved in hot water, filtered, and recrystallized three times.	
		(2) Water. Nothing specified.	
		ESTIMATED ERROR:	
		Temp.: Nothing specified.

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Stoppered flasks containing weighed amounts of $\text{Sr}(\text{OH})_2$ and water were agitated in a thermostat for an undefined amount of time. The saturated solution was filtered through a cotton plug or centrifugated when the precipitate grain size was too small to allow filtration. $\text{Sr}(\text{OH})_2$ was titrated with standard acid. The composition of the hydrate stable above 85°C was determined by a study of the $\text{Sr}(\text{OH})_2 + \text{NaBr} + \text{H}_2\text{O}$ system at 100°C . Analysis of both $\text{Sr}(\text{OH})_2$ saturated solution and wet precipitate confirmed the monohydrate, $\text{Sr}(\text{OH})_2 \cdot \text{H}_2\text{O}$.		(1) Strontium hydroxide. Commercial product from Merck, "free from barite." Used without further purification.

The paper also reports density, refractive index, electrical conductivity and viscosity of the above solutions.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The solubility in the $\text{Sr}(\text{OH})_2 + \text{Sr}(\text{NO}_2)_2 + \text{H}_2\text{O}$ system was studied isothermally at (25.0±0.1)°C in a water thermostat. It was confirmed that samples reached equilibrium after 34-36 h of continual stirring by analysis of liquid phase specimens. The equilibrium phases were analyzed for nitrite ion permanganatometrically, for hydroxide ion acidimetrically and for strontium ion complexometrically. References to the methods are in the paper. The composition of the solid phases was found by Schreinemakers' graphical method of residues and confirmed by chemical analysis.		(1) $\text{Sr}(\text{OH})_2$. Chemically pure grade used without recrystallization. The CO_3^{2-} ion content did not exceed 0.05 mass %.		
		(2) $\text{Sr}(\text{NO}_2)_2$. Prepared by double decomposition between $\text{Ba}(\text{NO}_2)_2$ and SrSO_4 . Recrystallized material analyzed 99.60 mass % anhydrous salt.		
		(3) water. Nothing specified.		
		ESTIMATED ERROR:		
		Temp.: Precision ± 0.1 K. Soly.: Nothing specified.		
		REFERENCES:		
The solubility in water was $\text{Sr}(\text{OH})_2$ 0.97 mass % and $\text{Ca}(\text{NO}_2)_2$ 41.58 mass %. The values agreed satisfactorily with published data (1, 2).		1. Protsenko, P. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
Solid $\text{Sr}(\text{OH})_2$ was added to aqueous $\text{Sr}(\text{NO}_3)_2$ solution in tightly stoppered bottles and rotated for four months at 25°C to attain equilibrium. Aliquots of saturated solution were removed and the $\text{Sr}(\text{OH})_2$ determined by titration with standard HNO_3 solution using phenolphthalein as indicator. The $\text{Sr}(\text{NO}_3)_2$ was determined by acidification of an aliquot with HNO_3 , evaporation to dryness, weighing the residue, and subtraction of the amount corresponding to $\text{Sr}(\text{OH})_2$.		(1) Strontium hydroxide. Prepared from pure SrO .		
		(2) Strontium nitrate. Commercial sample specially purified by separation of barium salt impurity.		
		ESTIMATED ERROR:

<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Salt and solution were stirred for 8 days in a thermostat. After equilibration, samples were removed for analysis through a pipet fitted with a glass wool filter. Density was measured using a pycnometer; the contents of which were then used for analysis of sulfate by volumetric or colorimetric methods. Viscosity was measured using a Vogel-Ossag viscometer and conductivity with a Philips bridge (CM 4249; average reading error 2 %) and dip cell. The author claims that there is no phase change in the equilibrium solid, which is $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Strontium hydroxide. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Sr(OH) ₂ and water are placed in a stoppered flask fitted with two tubes passing through the cork, one of them with a felt plug at the end. After some hours at the desired temperature, samples are withdrawn by forcing the solution through the felt plug. Sr(OH) ₂ is analyzed by acidimetry and the sucrose concentration measured by polarimetry. Temperatures are controlled by an ice bath (0°C), by flowing water (11 - 13°C), by a thermostated bath (40 - 90°C), and by boiling (101°C). 20 - 24°C are the ambient temperatures. Each experiment is repeated two or three times.		(1) Strontium hydroxide. Prepared from "Strontionite" (SrCO ₃ ore) ignited, dissolved in hot water, filtered, and recrystallized three times.	
		(2) Sucrose. Nothing specified.	
		(3) Water. Nothing specified.	
		ESTIMATED ERROR:	
		Temp.: Nothing specified.	
		Soly.: reproducibility < ± 6 % Sr(OH) ₂ (author).

Metastable equilibria were excluded.	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: Stoppered flasks containing weighed amounts of $\text{Sr}(\text{OH})_2$ and water were agitated in a thermostat for an undefined amount of time. The saturated solution was filtered through a cotton plug or centrifugated when the precipitate grain size was too small to allow filtration. $\text{Sr}(\text{OH})_2$ was titrated with standard acid. Sucrose was analyzed by polarimetry.	SOURCE AND PURITY OF MATERIALS: (1) Strontium hydroxide. Commercial product from Merck, "free from barite." Used without further purification. (2) Sucrose. Pure commercial sugar. (3) Water. Nothing specified. ESTIMATED ERROR: No estimates possible. REFERENCES:

CRITICAL EVALUATION:

An evaluation of the solubility of barium hydroxide in water and in various aqueous solutions.

The solubility of barium hydroxide in water and aqueous solutions is reported in 22 publications. The starting material, when its nature is described, is the well-crystallized hydrate, $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$.

1. The solubility of barium hydroxide in water.

Data for the solubility of $\text{Ba}(\text{OH})_2$ in water have been reported in 19 publications (1-5, 7, 8, 11, 13-17, 20-25). The solid phase in equilibrium with the saturated solution up to 353 K is $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$; at higher temperatures (25) it is $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$. Reynolds' (23) measurements, which are the result of student experiments, are of poor reproducibility, and may be rejected. Rosenthal and Ruhlman's (1) results at the lower temperatures agree well with the presently recommended values, their values are low at intermediate temperatures and high at high temperatures. Other rejected early data are given in Mellor (32).

The solubility data at temperatures below 353 K, for which $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ is the equilibrium solid, have been converted to molalities and are given in Table 1. Some of the data near room temperature (4, 7, 15 and 16) were given in concentration units which required knowledge of the density of the solution for conversion to molalities. There are few reliable data for the density of $\text{Ba}(\text{OH})_2$ solutions. We used the relative density value estimated by linear interpolation of the two d^{20} values reported in the *International Critical Tables* (26), ignoring the variation with temperature. The maximum error is estimated to be $\Delta d = \pm 0.01$ which would lead to an error in molality of:

$$\Delta m = 3.3 \times 10^{-3} \text{ mol kg}^{-1}.$$

The data were fitted by the method of least squares to a type of equation recommended in the "Introduction to the Solubility of Solids in Liquids", eqn [48], (see also (27)), with activity and osmotic coefficient terms included in the γ_m function. This equation is based on a thermodynamic treatment of saturated solutions and their equilibrated solid phases and has the form

$$\gamma_m = A_1 + A_2/(T/K) + A_3 \ln (T/K).$$

where $\gamma_m = \ln (m/m_o) - (m/m_o - 1)$ with $1/m_o = 0.144 \text{ kg mol}^{-1}$ at the congruent fusion temperature. When the usual procedure of discarding points which deviate by more than two standard deviations and repeating the fit was applied, the four points marked in table 1 were discarded.

The resulting fitting equation is:

$$\gamma_m = -225.404 + 6019.08/(T/K) + 35.0861 \ln (T/K) \quad [1]$$

with $s(\gamma_m) = 0.026$. The equation was used to calculate recommended solubility values at 5 degree intervals [$s(m) = 0.015$] from 273.15 to 348.15 K; see Table 2 and Fig. 1. The temperature calculated for the congruent melting point is 352.4 K with $s(T_m) = 0.6 \text{ K}$.

The solubility at 298 K is known with better precision than the 298 K value from the fitting equation. The experimental solubility is:

$$\begin{aligned} m[\text{Ba}(\text{OH})_2] &= 0.265 \text{ mol kg}^{-1} \text{ at } 298.15 \text{ K} \\ s(m) &= 0.009 \text{ mol kg}^{-1} \end{aligned}$$

Figure 1. The recommended solubility of barium hydroxide octahydrate as a function of temperature. Equation [1] and Table 2.

2. Barium hydroxide + electrolyte + water: ternary systems.

A. $\text{Ba}(\text{OH})_2 + \text{NaOH} + \text{H}_2\text{O}$ and $\text{Ba}(\text{OH})_2 + \text{KOH} + \text{H}_2\text{O}$

Studies of these systems were reported in seven papers (5, 15, 16, 20, 22, 24, 25). Insufficient data were obtained under the same conditions of temperature and concentration to recommend any set of values. Only qualitative observations can be made. Results given only as concentrations (15) were rejected because they could not be compared with the work of others. The 293 K isotherm was studied by both Scholder and Patsch (16) and by Mozharova and Kuznetsova (22). Their results are

(2) Water; H_2O ; [7732-18-5], and various aqueous solutions.	H. L. Clever Department of Chemistry Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

Table 2. Recommended values of the solubility of $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ in water between 273.15 and 348.15 K.

Temperature		Barium Hydroxide Solubility $m_1/\text{mol kg}^{-1}$
$t/^{\circ}\text{C}$	T/K	
0	273.15	0.10
5	278.15	0.12
10	283.15	0.15
15	288.15	0.18
20	293.15	0.22
25	298.15	0.27
30	303.15	0.33
35	308.15	0.41
40	313.15	0.51
45	318.15	0.64
50	323.15	0.81
55	328.15	1.04
60	333.15	1.35
65	338.15	1.78
70	343.15	2.42
75	348.15	3.53

compared in Fig. 2 and agree well up to $13 \text{ mol kg}^{-1} \text{ NaOH}$.

All workers, except Scholder and Pättsch (16), identified successively the three hydrates: $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$, $\text{Ba}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$ and $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$ as the NaOH concentration increases. At high temperatures only the monohydrate is stable. The same behavior is observed in KOH solution (24). Comparison of the results at different temperatures shows that the solubility of $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}(\text{s})$ increases with temperature in the 283 to 333 K range. The behavior of the lower two hydrates is not as clearly defined as shown in Fig. 1.

B. $\text{Ba}(\text{OH})_2 + \text{BaCl}_2 + \text{H}_2\text{O}$

Studies of this system were reported in six publications (5, 10, 17, 22, 24, 25, 31) of which three are from the same laboratory. Each paper reports data at a different temperature, thus no direct comparison of the results can be made. The phase diagrams at the different temperatures are consistent. The equilibrium solid phases observed as the BaCl_2 concentration increases are successively $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ (or $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$ at 353 K), $\text{BaClOH} \cdot \text{H}_2\text{O}$ and $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$.

The same equilibrium solids are obtained when HCl is a starting component in place of BaCl_2 (11). The system $\text{Ba}(\text{OH})_2 + \text{BaCl}_2 + \text{NaOH} + \text{NaCl} + \text{H}_2\text{O}$ exhibits the same compounds plus $\text{NaCl}(\text{s})$.

C. $\text{Ba}(\text{OH})_2 + \text{Barium salt} + \text{H}_2\text{O}$

The systems $\text{Ba}(\text{OH})_2 + \text{BaBr}_2 + \text{H}_2\text{O}$ and $\text{Ba}(\text{OH})_2 + \text{BaI}_2 + \text{H}_2\text{O}$ were studied by Schreinemakers and Milikan (31) and by Milikan (10). They behave qualitatively in the same manner as the $\text{Ba}(\text{OH})_2 + \text{BaCl}_2 + \text{H}_2\text{O}$ system. The absence of experimental details does not allow an evaluation of the data.

Only one source of data is available for each of the following four systems, and thus no evaluations are possible.

The system $\text{Ba}(\text{OH})_2 + \text{Ba}(\text{SH})_2 + \text{H}_2\text{O}$ was studied by Terres and Brückner (12) over the temperature interval 273 - 373 K. Its behavior is

COMPONENTS:

CRITICAL EVALUATION:

Figure 2. The solubility of barium hydroxide in aqueous sodium hydroxide solutions at several temperatures. References 5, 16 and 22.

<p>COMPONENTS:</p> <p>(1) Barium hydroxide; $\text{Ba}(\text{OH})_2$; [17194-00-2]</p> <p>(2) Water; H_2O; [7732-18-5], and various aqueous solutions.</p>	<p>EVALUATOR:</p> <p>Irma Lambert H. L. Clever CEA/SCECF/SECA Department of B. P. 6 Chemistry 92265 Fontenay- Emory University aux-Roses Cedex Atlanta, GA 30322 FRANCE USA November, 1991</p>
<p>CRITICAL EVALUATION:</p> <p>analogous to the previous systems in that there are three equilibrium solids: $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ (the authors do not mention lower hydrates at the higher temperatures), $\text{Ba}(\text{OH})_2 \cdot \text{Ba}(\text{SH})_2 \cdot 6\text{H}_2\text{O}$ and $\text{Ba}(\text{SH})_2 \cdot 6\text{H}_2\text{O}$. Unlike the systems containing barium halide, $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ is claimed to remain the stable solid phase over a larger range of $\text{Ba}(\text{SH})_2$ concentration when the temperature increases.</p> <p>Footte and Hickey (17) studied the systems $\text{Ba}(\text{OH})_2 + \text{Ba}(\text{SCN})_2 + \text{H}_2\text{O}$, $\text{Ba}(\text{OH})_2 + \text{Ba}(\text{CH}_3\text{COO})_2 + \text{H}_2\text{O}$ and $\text{Ba}(\text{OH})_2 + \text{Ba}(\text{ClO}_3)_2 + \text{H}_2\text{O}$ at 298 K. Parsons and Corson (6) studied the $\text{Ba}(\text{OH})_2 + \text{Ba}(\text{NO}_3)_2 + \text{H}_2\text{O}$ system at 298 K. In the systems containing thiocyanate and acetate ion a double salt exists as in the hydrosulfide case. In the systems containing chlorate and nitrate ion only barium hydroxide octahydrate and the anhydrous chlorate or nitrate salt exist as equilibrium solids.</p> <p>D. $\text{Ba}(\text{OH})_2 + \text{MCl} + \text{H}_2\text{O}$ ($\text{M} = \text{Li}, \text{Na}, \text{K}, \text{Rb}$)</p> <p>Herz (7) showed that the solubility of $\text{Ba}(\text{OH})_2$ increased on addition of alkali halides, with the effect decreasing from Li to Rb.</p> <p>E. $\text{Ba}(\text{OH})_2 + \text{Al}_2\text{O}_3 + \text{H}_2\text{O}$</p> <p>Malquori (13) studied the system at 293 K. The following solid phases were identified: $\text{BaO} \cdot 2\text{H}_2\text{O}$ (or $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$), $\text{Al}_2\text{O}_3 \cdot 2\text{BaO} \cdot 5\text{H}_2\text{O}$ (or $2\text{Al}(\text{OH})_3 \cdot 2\text{Ba}(\text{OH})_2$), $\text{Al}_2\text{O}_3 \cdot \text{BaO} \cdot 6\text{H}_2\text{O}$ (or $2\text{Al}(\text{OH})_3 \cdot \text{Ba}(\text{OH})_2 \cdot 2\text{H}_2\text{O}$) and $\text{Al}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ (or $\text{Al}(\text{OH})_3 \cdot x\text{H}_2\text{O}$).</p> <p>3. Barium hydroxide + organic component + water ternary systems.</p> <p>A. $\text{Ba}(\text{OH})_2 + \text{C}_{12}\text{H}_{22}\text{O}_{11}$ (Sucrose) + H_2O</p> <p>Nishizawa and Hachihama (14) studied the system over the 298 to 348 K temperature range. Three solid phases were reported at 298 and 318 K, depending on the sucrose concentration: $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$, $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot \text{BaO}$ (or $\text{C}_{12}\text{H}_{21}\text{O}_{11} \cdot \text{BaOH}$) and $\text{C}_{12}\text{H}_{22}\text{O}_{11}$. At 348 K $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot 3\text{BaO}$ was also reported. Rendelman (33) reviewed all metal oxide carbohydrate interactions and says they are either alcoholates or carbohydrate metal oxide (or hydroxide) adducts with reports of up to four BaO per saccharide unit.</p> <p>B. $\text{Ba}(\text{OH})_2 + \text{C}_6\text{H}_6\text{O}$ (Phenol) + H_2O and $\text{Ba}(\text{OH})_2 + \text{C}_6\text{H}_6\text{O}_2$ (1,3-Benzenediol) + H_2O</p> <p>Van Meurs (9) studied these systems and showed the formation of $\text{Ba}(\text{C}_6\text{H}_5\text{O})_2 \cdot 4\text{H}_2\text{O}$ in the first case and $\text{Ba}(\text{C}_6\text{H}_5\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$ in the second.</p> <p>C. $\text{Ba}(\text{OH})_2 + \text{C}_2\text{H}_6\text{O}$ (Ethanol) + H_2O</p> <p>Jankovic (19) studied the system up to 87.7 mol percent ethanol at 298 K. He claimed that barium hydroxide was the solid phase.</p> <p>D. $\text{Ba}(\text{OH})_2 + \text{C}_3\text{H}_6\text{O}$ (2-Propanone) + H_2O</p> <p>Herz and Knock (4) studied the system up to 70 volume % 2-propanone (acetone) at 298 K. The solubility decreased with increasing 2-propanone concentration. No mention is made of the composition of the solid. The authors' solubility value in water was rejected and the solubility values in the mixed solvent are considered doubtful.</p> <p>4. Non-aqueous systems</p> <p>A. $\text{Ba}(\text{OH})_2 + \text{C}_5\text{H}_4\text{O}$ (furfural)</p> <p>Trimble (18) measured the solubility of both the anhydrous and the octahydrate barium hydroxide in dry furfural. The octahydrate was more soluble. It is thought this is because the water of hydration makes the</p>	

COMPONENTS:	EVALUATOR:

(2) Water; H ₂ O; [7732-18-5], and various aqueous solutions	92265 Fontenay- aux-Roses Cedex FRANCE November, 1991	Emory University Atlanta, GA 30322 USA

CRITICAL EVALUATION:

system a mixed furfural + water solvent. The data are tentative.

5. Comparison of these results with other evaluations.

The present work evaluated the stoichiometric solubility of barium hydroxide. Two standard evaluations present information on the barium hydroxide solubility product and the barium ion and hydroxide ion association constant.

The authors of *Critical Stability Constants* (30) evaluated data from six sources. They give values of $\log K_{\text{assn}}$ of $\text{Ba}(\text{OH})^+(\text{aq})$ at three ionic strengths at 298.15 K which we summarize below:

$I/\text{mol dm}^{-3}$	0.0	0.1	3.0
$K_{\text{assn}}/\text{mol dm}^{-3}$	4.0	2.5	1.0

The authors also gave a value of $\log K_{\text{so}} = -3.6$ or $K_{\text{so}} = 2.5 \times 10^{-4}$ at zero ionic strength and 298.15 K for the $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ hydrate. Their enthalpy of solution is 57.3 kJ mol^{-1} .

Gibbs energy data given in the *Thermodynamic Tables* (29) also allows calculation of the $\text{Ba}(\text{OH})^+(\text{aq})$ formation constant at zero ionic strength and 298.15 K. The value is 155, substantially larger than the value in *Critical Stability Constants*.

We have a slight preference for the larger value which is based on thermodynamic information available to the authors of both works cited above.

The *Thermodynamic Tables* (29) do not have Gibbs energies of formation for $\text{Ba}(\text{OH})_2(\text{s})$ or its mono-, tri- or octahydrates. Thus no calculation of the solubility product is possible from that source.

6. Crystal structures of the barium hydroxide solids.

Characterization of the solid state in equilibrium with the saturated solution is an important part of any modern solubility study. The following information, mostly from the *Crystal Data Determinative Tables*, and Buchmeier and Lutz (34), is neither complete nor evaluated, but it serves as a reminder of this important point.

Crystal Formula	Type	Density/ Mg m^{-3}
BaO ; [1304-28-5]	Cubic	5.982
$\text{Ba}(\text{OH})_2$; [17194-00-2]	Amorphous	4.495
$\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$; [22326-55-2]	Orthorhombic Monoclinic	3.648 3.618
$\text{Ba}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$; [66905-77-9]	Orthorhombic	2.881
$\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$; [12230-71-6]	Monoclinic	2.061- 2.188

The Kirk-Othmer *Encyclopedia of Chemical Technology*, J. Wiley, New York, 1978, Vol. 3, states $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ melts in its own water of crystallization, i. e. peritectic temperature = 351.1 K (77.9°C) (vapor pressure 30.3 kPa). When further boiled under exclusion of atmospheric carbon dioxide the solution boils dry at a composition of $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$. Upon continuous heating a solid-phase transition to anhydrous $\text{Ba}(\text{OH})_2$, m. p. 678 K , occurs. On heating to red heat at about 1073 K water is split off and BaO is formed. It is further stated that the trihydrate may be a mixture of the mono- and octahydrates.

Mellor lists a number of early references on the solubility of Ba(OH)₂ in aqueous systems not included in this volume. We were unable to locate and check all of these references. The evaluator believes these references can be rejected because of impure components, failure to exclude carbon dioxide, and not using sufficient time to attain equilibrium.

Equilibrium solid BaO·9H₂O [Ba(OH)₂·8H₂O].

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The compilers calculated the Ba(OH)₂ mass % and molality values.

Water and excess crystals of barium hydroxide were placed in a vessel which was maintained in a large water bath of known temperature (not thermostated) for 2 to 10 hours. The solution was decanted, a sample taken, weighed and titrated with oxalic acid.

SOURCE AND PURITY OF MATERIALS:

(1) Barium hydroxide. Prepared by the reaction of ZnO on BaS in boiling water for 1.5 hours. The insoluble ZnS precipitates, is separated by decantation, and the barium hydroxide is crystallized from the solution by cooling.

(2) Water. Nothing specified.

ESTIMATED ERROR:

No estimates possible.

20	3.5	Ba(OH) ₂ ·3H ₂ O											
<p>The author compared his results with those of Rosenstiehl and Ruhlman (ref 1) for Ba(OH)₂·8H₂O at 10 and 20°C. They reported values of 2.2 and 3.48 mass % BaO, respectively for the two temperatures. The comparison led the author to conclude both hydrates have the same solubility.</p>													
AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE: The Ba(OH) ₂ ·3H ₂ O is added to CO ₂ free water. No other details are specified.	SOURCE AND PURITY OF MATERIALS: (1) Barium hydroxide. The Ba(OH) ₂ ·3H ₂ O is prepared by slow cooling from boiling Ba(OH) ₂ ·8H ₂ O. The starting material was the hydroxide, controlled by chemical analysis by the author and found to be 99.5 % purity. The octahydrate melts at 78°C, boils at 103 with an increase in temperature to 109 at which the trihydrate separate out.												
	ESTIMATED ERROR: No estimates possible.												
	REFERENCES: 1. Rosenstiehl, A.; Ruhlman, Bull. Soc. Mulhouse 1870, 40, 153; Forshritte Chem. 1870, 314.

The solubility of Ba(OH) ₂ in water as a function of pressure at 25°C				
Pressure	Barium Hydroxide			Comments
p/bar	Ba(OH) ₂ ·8H ₂ O mass %	Ba(OH) ₂ mass %	m ₁ /mol kg ⁻¹	
1	8.304	4.510	0.2754	a
1	8.295	4.505	0.2756	b
245	8.779	4.768	0.2924	a
245	8.802	4.780	0.2932	b
490	9.366	5.087	0.3130	c
Comments: a. Solution first saturated at 30, then cooled to 25°C (approach from over sat.). b. Solution first saturated at 20, then warmed to 25°C (approach from under sat.). c. no information.				
Solid phase in equilibrium with saturated solution was Ba(OH) ₂ ·8H ₂ O.				
The molal solubility of Ba(OH) ₂ was calculated by the compiler assuming the mass % referred to Ba(OH) ₂ ·8H ₂ O. He also calculated mass % Ba(OH) ₂ .				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
Mixtures of Ba(OH) ₂ and H ₂ O were equilibrated at either 20 or 30°C for 0.5 hour then 2-3 hours at 25°C in a U-tube type pressure bomb which permitted solution sample withdrawing without pressure relief. The Ba(OH) ₂ content of the saturated solution was determined by titration with standard HCl solution.		(1) Barium hydroxide. Chemically pure Ba(OH) ₂ ·8H ₂ O was used.		
NOTE: The author labeled the pres- sure unit as megabar and used definition Megabar = 10 ⁶ dynes = 1.02 kg cm ⁻²		(2) Water. Nothing specified.		
The compilers used 1 bar = 1.02 kg cm ⁻² and labeled pressure column bar.		ESTIMATED ERROR:		
p/bar p/kg cm ⁻² p/MPa p/atm		No estimates possible.

Solid phase recovered on drying at room temperature was Ba(OH) ₂ ·H ₂ O (Method A).			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Method A. Distilled water was saturated with Ba(OH) ₂ ·8H ₂ O by shaking. After equilibration, the residual solid phase was filtered (the filtrate was reserved for Method B); it was dried for two days and then weighed. The solubility, c ₁ , and the solubility product, K _{s0} = 4c ₁ ³ , were calculated. All procedures were carried out at a not specified room temperature.		(1) Barium hydroxide. Specified to be the hydrate Ba(OH) ₂ ·8H ₂ O.	
		(2) Water. Distilled.	
Method B. The filtrate reserved in Method A was titrated with standard HNO ₃ to determine the [OH ⁻], from which the solubility product was calculated from K _{s0} = (1/2)[OH ⁻] ³ .		ESTIMATED ERROR:	
Method C. Methods A and B were carried out at an elevated temperature using a water bath for preparation of the saturated solution.		No estimates possible.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

$\text{Ba}(\text{OH})_2$ and $\text{Ba}(\text{ClO}_3)_2$ were equilibrated with water at $25.00 \pm 0.03^\circ\text{C}$ by stirring for several days. Aliquots of saturated solution were analyzed for $\text{Ba}(\text{OH})_2$ by titration with standard HCl solution using nitrazine yellow as an indicator. Total Ba^{2+} in solution was determined by evaporating with HCl and weighing as BaCl_2 .

Solid Phases: A. Ba(OH) ₂ · 8H ₂ O			
B. Ba(OH) ₂ · Ba(SH) ₂ · 10H ₂ O or Ba(OH)(SH) · 5H ₂ O			
C. Ba(SH) ₂ · 4H ₂ O			
The solid phase was identified by inspection of Fig. 4 in the original paper. There is uncertainty in identifying the exact solution composition at which the solid changes composition.			
The paper also gives the solubility of Ba(SH) ₂ · 4H ₂ O in pure water from -15 to 100°C.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Solutions of Ba(OH) ₂ and Ba(SH) ₂ are mixed and allowed to stand overnight after the precipitation takes place.		Technical commercial products are used. The Ba(SH) ₂ is obtained by hydrolysis of BaS.	
Analysis of solution: Sulfide is oxidized into sulfate by H ₂ O ₂ which precipitates as BaSO ₄ . BaSO ₄ is precipitated from the remaining solution by addition of either BaCl ₂ or H ₂ SO ₄ depending on which species is in excess. The BaSO ₄ is determined gravimetrically.		ESTIMATED ERROR:	
Analysis of solid: The solid is dissolved in water and titrated with standard HCl solution using phenolphthalein (titration of OH ⁻) and methyl orange (titration of SH ⁻) as indicators.		No estimates possible

Solid Phases: A Ba(OH) ₂ ·8H ₂ O; B Ba(NO ₃) ₂				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
Solid Ba(OH) ₂ was added to aqueous Ba(NO ₃) ₂ solution in tightly stoppered bottles and rotated for four months at 25°C to attain equilibrium. Aliquots of saturated solution were removed and the Ba(OH) ₂ determined by titration with standard HNO ₃ solution using phenolphthalein as indicator. The Ba(NO ₃) ₂ was determined by acidification of an aliquot with HNO ₃ , evaporation to dryness, weighing the residue, and subtraction of the amount corresponding to Ba(OH) ₂ .		(1) Barium hydroxide. (2) Barium nitrate. Specially pure samples of each component were used.		
		ESTIMATED ERROR:		
		No estimates possible.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

$\text{Ba}(\text{OH})_2$ and $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$ were equilibrated with water at $25.00 \pm 0.03^\circ\text{C}$ by stirring for several days. Aliquots of saturated solution were analyzed for $\text{Ba}(\text{OH})_2$ by titration with standard HCl solution using phenolphthalein as an indicator. Total Ba^{2+} in solution was determined by evaporating with HCl and weighing as BaCl_2 .

SOURCE AND PURITY OF MATERIALS:

- (1) Barium hydroxide. Recrystallized before use.
- (2) Barium acetate. Recrystallized before use.
- (3) Water.

C. Al ₂ O ₃ ·BaO·6H ₂ O D. Al ₂ O ₃ ·xH ₂ O					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
Mixtures of Al ₂ O ₃ ·2BaO·5H ₂ O and Ba(OH) ₂ or γ-Al ₂ O ₃ in water are allowed to equilibrate in a thermostated bath at 20°C. The equilibration time is about one month. The solid phase was separated by filtration, and the solution analyzed for aluminum as Al ₂ O ₃ and for barium as BaSO ₄ .			(1) Barium hydroxide. Nothing specified.		
If mixtures of Al ₂ O ₃ and Ba(OH) ₂ in water are used, the equilibration time is much longer (about five months).			(2) Barium aluminate. Prepared by reaction of Al ₂ O ₃ on a sat. soln. of Ba(OH) ₂ at the boiling point. The solution is conc. by distillation and the product crystallizes from solution.		
			(3) Aluminum oxide. Three methods. α: reaction of NH ₄ OH with AlCl ₃ or Al(NO ₃) ₃ . β: reaction of CO ₂ on Na or K aluminate. γ: hydrolysis of barium aluminate. In all three cases the product was dried at 150°C.		
			ESTIMATED ERROR:		
			No estimates possible

VARIABLES:		PREPARED BY:	
T/K = 298 Concentration of LiCl, NaCl, KCl, and RbCl.		I. Lambert	
EXPERIMENTAL VALUES:			
The solubility of Ba(OH) ₂ in aqueous alkali halide solutions at 25°C			
Alkali Halide	Cl ⁻	OH ⁻	Ba(OH) ₂
	c/mol L ⁻¹	c/mol L ⁻¹	c ₁ /mol L ⁻¹
Lithium chloride; LiCl [7447-41-8]	0 0.75 1.42 2.3	0.555 0.745 0.937 1.336	0.278 0.373 0.468 0.668
Sodium chloride; NaCl; [7647-14-5]	0 0.73 1.43 2.82	0.555 0.630 0.699 0.806	0.278 0.315 0.350 0.403
Potassium chloride; KCl; [7447-40-7]	0 0.86 1.75 8.4	0.555 0.645 0.660 0.676	0.278 0.323 0.330 0.338
Rubidium chloride; RbCl; [7791-11-9]	0 1.25	0.555 0.648	0.278 0.324
The compiler calculated the solubility of Ba(OH) ₂ from the relation: cBa(OH) ₂ = (1/2)cOH ⁻ .			
The greater increase of Ba(OH) ₂ solubility in LiCl solutions compared to NaCl, KCl, and RbCl solutions was attributed by the author to the lower dissociation of LiOH compared with other alkali hydroxides.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Excess Ba(OH) ₂ ·8H ₂ O was stirred with the salt solution until saturation was attained. After decantation, an aliquot of saturated solution was removed by aspiration. The hydroxide ion was determined by titration with standard sulfuric acid solution using phenolphthalein indicator, and the chloride ion was determined by titration with standard silver nitrate solution using potassium chromate indicator.		Nothing specified.	
		ESTIMATED ERROR:	
		Error on OH ⁻ and Cl ⁻ determinations is estimated by the author to be less than 1 %.

Solid Phases: A Ba(OH) ₂ ·8H ₂ O; B Ba(OH) ₂ ·4H ₂ O; C Ba(OH) ₂ ·1.5H ₂ O; D Ba(OH) ₂ ·H ₂ O.			
The authors noted Ba(OH) ₂ was weakly amphoteric.			
The compiler calculated the Ba(OH) ₂ concentrations.			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Aqueous solutions of Ba(OH) ₂ and NaOH were mixed and equilibrated in a closed Ni coated Cu vessel at 20.0 ± 0.02°C for 7-14 days with stirring. The solid phase was filtered off under a N ₂ atm, and an excess of standard HCl added. The OH ⁻ was detd. by backtitration with standard NaOH solution. The Ba ²⁺ in the filtrate was determined as sulfate by gravimetry. The NaOH concentration detd by difference.		(1) Barium hydroxide. Ba(OH) ₂ ·8H ₂ O was used.	
		(2) Sodium hydroxide. Pure NaOH was dissolved in water to >50 mass % and filtered to remove insoluble carbonate before use.	
		ESTIMATED ERROR:	
		Temp.: precision ± 0.02 K. Soly.: No estimates possible.

COMPONENTS: (1) Barium hydroxide; $\text{Ba}(\text{OH})_2$; [17194-00-2] (2) Sucrose; $\text{C}_{12}\text{H}_{22}\text{O}_{11}$; [57-50-1] (3) Water; H_2O ; [7732-18-5]	ORIGINAL MEASUREMENTS: Nishizawa, K.; Hachihama, Y. <i>Z. Elektrochem. Angew. Phys. Chem.</i> <u>1929</u> , 35, 385-92.
VARIABLES: $T/K = 298, 318, \text{ and } 348$ Composition	PREPARED BY: H. Einaga Y. Komatsu
EXPERIMENTAL VALUES: ADDITIONAL DATA AND/OR COMMENTS: Phase Diagrams at 25 and 75°C. <div style="display: flex; justify-content: space-around; align-items: center;">   </div>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: Sucrose and $\text{Ba}(\text{OH})_2$ aqueous mixtures were equilibrated within $\pm 0.05^\circ\text{C}$ at a specified temperature for 2 - 4 days at 25 and 45°C and for 8 - 12 hours at 75°C . Aliquots of saturated solution were analyzed for $\text{Ba}(\text{OH})_2$ gravimetrically as BaSO_4 , and for sucrose by the method of Quinsumbing and Thomas (ref 1) after neutralization with HCl followed by inversion by the Soxhlet method (ref 2).	SOURCE AND PURITY OF MATERIALS: (1) Barium hydroxide. Analytical grade, purified by recrystallization from water. (2) Sucrose. Purified by recrystallization from aqueous ethanol. (3) Water. Distilled CO_2 free water.
ESTIMATED ERROR: No estimates possible.

SYSTEM INDEX

Page numbers preceded by E refer to evaluation texts whereas those not preceded by E refer to compiled tables. Substances are index as in Chemical Abstracts, for example ammonium acetate is indexed under acetic acid, ammonium salt.

Acetic acid, ammonium salt (multicomponent)	
+ acetic acid, magnesium salt	E52, 100
+ ammonia	E52, 100
+ magnesium hydroxide	E52, 100
Acetic acid, barium salt (aqueous)	
+ barium hydroxide	E290, 323
Acetic acid, magnesium salt (multicomponent)	
+ acetic acid, ammonium salt	E52, 100
+ ammonia	E52, 100
+ magnesium hydroxide	E52, 100
Acetic acid, sodium salt (aqueous)	
+ calcium hydroxide	E116, E117, 219
Aluminium oxide (multicomponent)	
+ barium aluminium oxide	E290, 325
+ barium hydroxide	E290, 325
Ammonia (aqueous)	
+ calcium hydroxide	157
+ strontium hydroxide	E254, 272
Ammonia (multicomponent)	
+ acetic acid, ammonium salt	E52, 100
+ acetic acid, magnesium salt	E52, 100
+ ammonium chloride	E52, 77, 86, 87
+ magnesium chloride	E52, 86, 87
+ magnesium hydroxide	E52, 77, 86, 87, 93-95, 100
+ nitric acid, ammonium salt	E52, 95
+ nitric acid, magnesium salt	E52, 95
+ sulfuric acid, ammonium salt	E52, 93
+ sulfuric acid, magnesium salt	E52, 93
+ thiocyanic acid, ammonium salt	E52, 94
+ thiocyanic acid, magnesium salt	E52, 94
Ammonium chloride (aqueous)	
+ calcium hydroxide	E119, 158
Ammonium chloride (multicomponent)	
+ ammonia	E52, 77, 86, 87
+ magnesium chloride	E52, 86, 87
+ magnesium hydroxide	E52, 77, 86, 87
Barium aluminium oxide (multicomponent)	
+ aluminium oxide	E290, 325
+ barium hydroxide	E290, 325
Barium bromide (aqueous)	
+ barium hydroxide	166, E288, 318
Barium chloride (aqueous)	
+ barium hydroxide	166, E288, 300-308
+ calcium hydroxide	E117, 196
Barium chloride (multicomponent)	
+ barium hydroxide	E287-E289, 309-316
+ hydrochloric acid	E288, 309-310
+ sodium chloride	E287-E289, 311-316
+ sodium hydroxide	E287-E289, 311-316

Barium hydrosulfide (aqueous)	
+ barium hydroxide	E288, E290, 320, 321
Barium hydroxide	
+ 2-furancarboxaldehyde	E290, E291, 247
+ phenol	E290, 337, 339
+ water	E284-E294, 295-299
Barium hydroxide (aqueous)	
+ 1,2-benzenediol	E290, 338, 339
+ acetic acid, barium salt	E290, 323
+ barium bromide	166, E288, 318
+ barium chlorate	E290, 317
+ barium chloride	166, E288, 300-308
+ barium hydrosulfide	E288, E290, 320, 321
+ barium iodide	166, E288, 319
+ ethanol	E290, 334-335
+ lithium chloride	E290, 326
+ nitric acid, barium salt	E290, 322
+ nitrous acid, barium salt	188
+ potassium chloride	E290, 326
+ potassium hydroxide	E287, E288, 333
+ rubidium chloride	E290, 326
+ sodium chloride	E290, 326
+ sodium hydroxide	E287-E289, 308, 327-329
+ sucrose	E290, 340-342
+ thiocyanic acid, barium salt	E290, 324
Barium hydroxide (multicomponent)	
+ aluminium oxide	E290, 325
+ barium aluminium oxide	E290, 325
+ barium chloride	E287-E289, 309-316
+ hydrochloric acid	E288, 309-310
+ magnesium chloride	E52, E53, 90, 91
+ magnesium hydroxide	E52, E53, 90, 91
+ sodium chloride	E287-E289, 311-316
+ sodium hydroxide	E287-E289, 311-316
Barium iodide (aqueous)	
+ barium hydroxide	166, E288, 319
+ barium oxide	166, E291
Beryllium bromide (multicomponent)	
+ beryllium hydroxide	E6, 25, 26
+ hydrobromic acid	E6, 25, 26
+ sodium hydroxide	E6, 25, 26
Beryllium chloride (multicomponent)	
+ beryllium hydroxide	E6, 23, 24
+ sodium hydroxide	E6, 23, 24
Beryllium hydroxide	
+ water	E1-E11, 12-15
Beryllium hydroxide (aqueous)	
+ hydrogen chloride	E2, 19
+ nitric acid	22
+ nitric acid, beryllium salt	E6, 33
+ nitric acid, sodium salt	E6, 48
+ perchloric acid	E6, 20, 21
+ perchloric acid, sodium salt	E5, E6, 44
+ sodium hydroxide	E2-E6, 34-41
+ sulfuric acid, beryllium salt	E6, 29
Beryllium hydroxide (multicomponent)	
+ beryllium bromide	E6, 25, 26
+ beryllium iodide	E6, 27, 28

Beryllium hydroxide (multicomponent)	
+ beryllium chloride	E6, 23, 24
+ carbonic acid, disodium salt	E5, E6, 46
+ carbonic acid, monosodium salt	E5, E6, 43, 45
+ citric acid	E6, 47
+ hydrobromic acid	E6, 25, 26
+ hydroiodic acid	E6, 27, 28
+ perchloric acid, sodium salt	E5, E6, 45-47
+ potassium hydroxide	E6, 32
+ sodium fluoride	E5, E6, 43
+ sodium hydroxide	E6, 23-28, 30, 31
+ sulfuric acid, beryllium salt	E6, 30-32
Beryllium iodide (multicomponent)	
+ beryllium hydroxide	E6, 27, 28
+ hydroiodic acid	E6, 27, 28
+ sodium hydroxide	E6, 27, 28
Beryllium oxide (aqueous)	
+ hydrogen fluoride	E6, 16, 17, 18
Beryllium oxide (multicomponent)	
+ hydrogen fluoride	E6, 18
+ nitric acid	E6, 18
+ sodium fluoride	E6, 42
+ sodium hydroxide	E6, 42
Boric acid (aqueous)	
+ calcium hydroxide	E120, 159-161
+ magnesium hydroxide	E60, 78
2-Butanol, 2-methyl- (aqueous)	
+ strontium hydroxide	E254, 272
Calcium bromide (aqueous)	
+ calcium hydroxide	E119, E120, 166, 181-183
Calcium chloride (aqueous)	
+ calcium hydroxide	E119, E120, 163- 174
Calcium chloride (multicomponent)	
+ calcium hydroxide	E52, E53, 88, 89, E119, E120, E122, 175-178, 245, 246
+ hydrochloric acid	E119, 175, 176
+ magnesium chloride	E52, E53, 88, 89
+ magnesium hydroxide	E52, E53, 88, 89
+ sodium chloride	E119, E120, E122, 177, 178, 245, 246
+ sucrose	E120, E122, 245, 246
Calcium hydroxide	
+ water	E113-E130, 131-155
Calcium hydroxide (aqueous)	
+ acetic acid, sodium salt	E116, E117, 219
+ ammonia	157
+ ammonium chloride	E119, 158
+ barium chloride	E117, 196
+ boric acid	E120, 159-161
+ calcium bromide	E119, E120, 166, 181-183
+ calcium chloride	E119, E120, 163-174
+ calcium iodide	E119, E120, 184
+ cesium chloride	E116, E117, 225
+ chloric acid, sodium salt	E116, E117, 209
+ ethanol	E122, 229, 230
+ 2-furancarboxaldehyde	E122, E124, 247
+ hypochlorous acid, calcium salt	E120, 179, 180
+ lithium chloride	E116, E117, 199

Calcium hydroxide (aqueous)	
+ lithium hydroxide	E116, 197, 198
+ magnesium hydroxide	E120, 162
+ methanol	E122, 226-228
+ nitric acid, calcium salt	E120, E121, 189-194
+ nitric acid, sodium salt	E116-E118, 214-218
+ nitrous acid, calcium salt	188
+ nitrous acid, sodium salt	E116, E117, 213
+ perchloric acid, sodium salt	E116, E117, 210
+ phenol	E122, 234, 235
+ potassium bromide	E118, 224
+ potassium chloride	E116-E118, 208, 221-223
+ potassium hydroxide	E116, 220
+ 1,2,3-propanetriol	E122, E123, 231, 232
+ sodium bromide	E116, E117, 211
+ sodium chloride	E116-E118, 203-208
+ sodium iodide	E116, E117, 212
+ strontium chloride	E117, 195
+ sucrose	E120, E122, 236-242
+ sulfuric acid, calcium salt	E120, 185
+ water-d2	E120, 156
Calcium hydroxide (multicomponent)	
+ calcium chloride	E52, E53, 88, 89, E119, E120, E122, 175-178, 245, 246
+ calcium oxide	E120, E122, 243, 244
+ formaldehyde	E122, 233
+ formic acid, calcium salt	E122, 233
+ hydrochloric acid	E119, 175, 176
+ magnesium chloride	E52, E53, 88, 89
+ magnesium hydroxide	E52, E53, 88, 89
+ potassium hydroxide	E120, 186, 187
+ sodium chloride	E116, E119, E120, E122, 177, 178, 202, 245, 246
+ sodium hydroxide	E116, E123, 186, 187, 202, 233
+ sucrose	E120, E122, 243-246
+ sulfuric acid, calcium salt	E120, 186, 187
Calcium iodide (aqueous)	
+ calcium hydroxide	E119, E120, 184
Calcium oxide (multicomponent)	
+ calcium hydroxide	E120, E122, 243, 244
+ sucrose	E120, E122, 243, 244
Carbon dioxide (multicomponent)	
+ carbonic acid, magnesium salt	E52, 98, 99
+ magnesium hydroxide	E52, 98, 99
Carbonic acid, calcium salt (aqueous)	
+ magnesium hydroxide	E51, 101
Carbonic acid, disodium salt (multicomponent)	
+ beryllium hydroxide	E5, E6, 46
+ perchloric acid, sodium salt	E5, E6, 46
Carbonic acid, magnesium salt (multicomponent)	
+ carbon dioxide	E52, 98, 99
+ magnesium hydroxide	E52, 98, 99

Carbonic acid, monosodium salt (multicomponent)	
+ beryllium hydroxide	E5, E6, 43
+ beryllium hydroxide	E5, E6, 45
+ perchloric acid, sodium salt	E5, E6, 45
+ sodium fluoride	E5, E6, 43
Cesium chloride (aqueous)	
+ calcium hydroxide	E116, E117, 225
Chloric acid, barium salt (aqueous)	
+ barium hydroxide	E290, 317
Chloric acid, sodium salt (aqueous)	
+ calcium hydroxide	E116, E117, 209
Chromium oxide (multicomponent)	
+ magnesium hydroxide	E60, 79, 80
+ magnesium oxide	E60, 79, 80
Citric acid (multicomponent)	
+ beryllium hydroxide	E6, 47
+ perchloric acid, sodium salt	E6, 47
Ethane, 1,1'-oxybis-	
+ strontium hydroxide	E254, 272
1,2-Ethanediol (aqueous)	
+ strontium hydroxide	E254, 272
Ethanol (aqueous)	
+ barium hydroxide	E290, 334, 335
+ calcium hydroxide	E122, 229, 230
+ magnesium hydroxide	E60, 111
+ strontium hydroxide	E254, 270-272
N-Ethylethanamine (aqueous)	
+ strontium hydroxide	E254, 272
Formaldehyde (multicomponent)	
+ calcium formate	E122, 233
+ calcium hydroxide	E122, 233
+ sodium hydroxide	E122, 233
Formic acid, calcium salt (multicomponent)	
+ calcium hydroxide	E122, 233
+ formaldehyde	E122, 233
+ sodium hydroxide	E122, 233
2-Furancarboxaldehyde	
+ barium hydroxide	E290, E291, 247
+ calcium hydroxide	E122, E124, 247
Glucose (aqueous)	
+ magnesium hydroxide	E60
Hydrobromic acid (multicomponent)	
+ beryllium bromide	E6, 25, 26
+ beryllium hydroxide	E6, 25, 26
+ sodium hydroxide	E6, 25, 26
Hydrochloric acid (aqueous)	
+ beryllium hydroxide	E2, 19
+ magnesium hydroxide	E56-E58, 102, 103
Hydrochloric acid (multicomponent)	
+ barium chloride	E288, 309-310
+ barium hydroxide	E288, 309-310
+ calcium chloride	E119, 175, 176
+ calcium hydroxide	E119, 175, 176
+ strontium chloride	E253, 263
+ strontium hydroxide	E253, 263
Hydrogen fluoride (aqueous)	
+ beryllium oxide	E6, 16, 17
Hydrogen fluoride (multicomponent)	
+ beryllium oxide	E6, 18
+ nitric acid	E6, 18
Hydrogen peroxide (aqueous)	
+ magnesium hydroxide	E58, 74, 75

Hydroiodic acid (multicomponent)	
+ beryllium hydroxide	E6, 27, 28
+ beryllium iodide	E6, 27, 28
+ sodium hydroxide	E6, 27, 28
Hypochlorous acid, calcium salt (aqueous)	
+ calcium hydroxide	E120, 179, 180
Lithium chloride (aqueous)	
+ barium hydroxide	E290, 326
+ calcium hydroxide	E116, E117, 199
+ magnesium hydroxide	E51, E53, E54, 105
Lithium hydroxide (aqueous)	
+ calcium hydroxide	E116, 197, 198
Magnesium chloride (aqueous)	
+ magnesium hydroxide	E52, E53, 81-85
Magnesium chloride (multicomponent)	
+ ammonia	E52, 86, 87
+ ammonium chloride	E52, 86, 87
+ barium hydroxide	E52, E53, 90, 91
+ calcium chloride	E52, E53, 88, 89
+ calcium hydroxide	E52, E53, 88, 89
+ magnesium hydroxide	E52, E53, 86-91
Magnesium hydroxide	
+ water	E50-E64, 65-73
Magnesium hydroxide (aqueous)	
+ boric acid	E60, 78
+ calcium hydroxide	E120, 162
+ carbonic acid, calcium salt	E51, 101
+ ethanol	E60, 111
+ glucose + water	E60
+ hydrochloric acid	E56-E58, 102, 103
+ hydrogen peroxide	E58, 74, 75
+ lithium chloride	E51, E53, E54, 105
+ magnesium chloride	E52, E53, 81-85
+ methanol	E60, 110
+ nitric acid, ammonium salt	E52, 76
+ nitric acid, sodium salt	E56-E58, 102, 103
+ perchloric acid, sodium salt	E56, 108
+ potassium bromide	E51, E53, E54, 105
+ potassium chloride	E51, E53, E54, 104, 105
+ potassium hydroxide	E51, E53, E54, 105
+ potassium iodide	E51, E53, E54, 105
+ sodium chloride	E51, E53, E54, E56-E58, 102-105
+ sulfuric acid, magnesium salt	E59, 92
+ sulfuric acid, potassium salt	E51, E53, E54, 105
+ sulfuric acid, sodium salt	E50, E51, E53, E56-E58, 105, 109
Magnesium hydroxide (multicomponent)	
+ acetic acid, ammonium salt	E52, 100
+ acetic acid, magnesium salt	E52, 100
+ ammonia	E52, 77, 86, 87, 93-95, 100
+ ammonium chloride	E52, 77, 86, 87
+ barium hydroxide	E52, E53, 90, 91
+ calcium chloride	E52, E53, 88, 89
+ calcium hydroxide	E52, E53, 88, 89

Magnesium hydroxide (multicomponent)	
+ carbon dioxide	E52, 98, 99
+ carbonic acid, magnesium salt	E52, 98, 99
+ thiocyanic acid, ammonium salt	E52, 94
+ chromium oxide	E60, 79, 80
+ magnesium chloride	E52, 86-91
+ magnesium oxide	E60, 79, 80
+ magnesium sulfocyanate	E52, 94
+ nitric acid, ammonium salt	E52, 95
+ nitric acid, magnesium salt	E52-E54, 95-97
+ nitric acid, sodium salt	E53, E54, 96, 97
+ sodium chloride	E54, 106, 107
+ sodium hydroxide	E54, 106, 107
+ sulfuric acid, ammonium salt	E52, 93
+ sulfuric acid, magnesium salt	E52, 93
Magnesium oxide (multicomponent)	
+ chromium oxide	E60, 79, 80
+ magnesium hydroxide	E60, 79, 80
D-Mannitol (aqueous)	
+ strontium hydroxide	E254, 272
Methanol (aqueous)	
+ calcium hydroxide	E122, 226-228
+ magnesium hydroxide	E60, 110
+ strontium hydroxide	E254, 272
Nitric acid (aqueous)	
+ beryllium hydroxide	22
Nitric acid (multicomponent)	
+ beryllium oxide	E6, 18
+ hydrogen fluoride	E6, 18
Nitric acid, ammonium salt (aqueous)	
+ magnesium hydroxide	E52, 76
Nitric acid, ammonium salt (multicomponent)	
+ ammonia	E52, 95
+ magnesium hydroxide	E52, 95
+ nitric acid, magnesium salt	E52, 95
Nitric acid, barium salt (aqueous)	
+ barium hydroxide	E290, 322
Nitric acid, beryllium salt (aqueous)	
+ beryllium hydroxide	E6, 33
Nitric acid, calcium salt (aqueous)	
+ calcium hydroxide	E120, E121, 189-194
Nitric acid, magnesium salt (multicomponent)	
+ ammonia	E52, 95
+ magnesium hydroxide	E52-E54, 95-97
+ nitric acid, ammonium salt	E52, 95
+ nitric acid, sodium salt	E53, E54, 96, 97
Nitric acid, sodium salt (aqueous)	
+ beryllium hydroxide	E6, 48
+ calcium hydroxide	E116-E118, 214-218
+ magnesium hydroxide	E56-E58, 102, 103
Nitric acid, sodium salt (multicomponent)	
+ magnesium hydroxide	E53, E54, 96, 97
+ nitric acid, magnesium salt	E53, E54, 96, 97
Nitric acid, strontium salt (aqueous)	
+ strontium hydroxide	E253, 269
Nitrous acid, barium salt (aqueous)	
+ barium hydroxide	188
Nitrous acid, calcium salt (aqueous)	
+ calcium hydroxide	188
Nitrous acid, sodium salt (aqueous)	
+ calcium hydroxide	E116, E117, 213
Nitrous acid, strontium salt (aqueous)	
+ strontium hydroxide	188, 268

Perchloric acid (aqueous) + beryllium oxide	E6, 20
Perchloric acid, sodium salt (aqueous) + beryllium hydroxide + calcium hydroxide + magnesium hydroxide	E5, E6, 44 E116, E117, 210 E56, 108
Perchloric acid, sodium salt (multicomponent) + beryllium hydroxide + carbonic acid, disodium salt + carbonic acid, monosodium salt + citric acid	E5, E6, 43, 45-47 E5, E6, 46 E5, E6, 45 E6, 47
Phenol (aqueous) + barium hydroxide + calcium hydroxide	E290, 337, 339 E122, 234, 235
Potassium bromide (aqueous) + calcium hydroxide + magnesium hydroxide + calcium hydroxide	E118, 224 E51, E53, E54, 105 E118, 224
Potassium chloride (aqueous) + barium hydroxide + calcium hydroxide	E290, 326 E116-E118, 208, 221-223
Potassium hydroxide (aqueous) + calcium hydroxide + magnesium hydroxide	E116, 220 E51, E53, 105
Potassium hydroxide (multicomponent) + beryllium hydroxide + calcium hydroxide + sodium hydroxide + sulfuric acid, beryllium salt + sulfuric acid, calcium salt	E6, 32 E120, 186, 187 E120, 186, 187 E6, 32 E120, 186, 187
Potassium iodide (aqueous) + magnesium hydroxide	E51, E53, E54, 105
Potassium sulfate (aqueous) + magnesium hydroxide	E51, E53, E54, 105
1,2,3-Propanetriol (aqueous) + calcium hydroxide + strontium hydroxide	E122, E123, 231, 232 E254, 272
1-Propanol + strontium hydroxide	E254, 272
2-Propanone (aqueous) + strontium hydroxide	E254, 272
Pyridine (aqueous) + strontium hydroxide	E254, 272
Rubidium chloride (aqueous) + barium hydroxide	E290, 326
Sodium bromide (aqueous) + calcium hydroxide	E116, E117, 211
Sodium chloride (aqueous) + barium hydroxide + calcium hydroxide + magnesium hydroxide	E290, 326 E116-E118, 203-208 E51, E53, E54, E56-E58, 102-105
Sodium chloride (multicomponent) + barium chloride + barium hydroxide + calcium chloride + calcium hydroxide	E287-E289, 311-316 E287-E289, 311-316 E119, E120, E122, 177, 178, 245, 246 E116, E119, E120, E122, 177, 178, 202, 245, 246

Sodium chloride (multicomponent)	
+ magnesium hydroxide	E54, 106, 107
+ sodium hydroxide	E54, 106, 107, E116, 202, E287-E289, 311-316
+ sucrose	E120, E122, 245, 246
Sodium fluoride (multicomponent)	
+ beryllium hydroxide	E5, E6, 42, 43
+ carbonic acid, monosodium salt	E5, E6, 43
+ perchloric acid, sodium salt	E5, E6, 43
+ sodium hydroxide	E5, E6, 42
Sodium hydroxide (aqueous)	
+ beryllium hydroxide	E2-E6, 34-42
Sodium hydroxide (multicomponent)	
+ barium chloride	E287-E289, 311-316
+ barium hydroxide	E287-E289, 311-316
+ beryllium bromide	E6, 25, 26
+ beryllium chloride	E6, 23, 24
+ beryllium hydroxide	E6, 23-28, 30, 31
+ beryllium iodide	E6, 27, 28
+ beryllium oxide	E6, 42
+ calcium hydroxide	E116, E123, 186, 187, 202, 233
+ formaldehyde	E122, 233
+ formic acid, calcium salt	E122, 233
+ hydrobromic acid	E6, 25, 26
+ hydroiodic acid	E6, 27, 28
+ magnesium hydroxide	E54, 106, 107
+ potassium hydroxide	E120, 186, 187
+ sodium chloride	E54, 106, 107, E116, 202, E287-E289, 311-316
+ sodium fluoride	E6, 42
+ sulfuric acid, beryllium salt	E6, 30, 31
+ sulfuric acid, calcium salt	E120, 186, 187
Sodium iodide (aqueous)	
+ calcium hydroxide	E116, E117, 212
Strontium bromide (aqueous)	
+ strontium hydroxide	E253, 264
Strontium chloride (aqueous)	
+ calcium hydroxide	E117, 195
+ strontium hydroxide	E253, 261, 262
Strontium chloride (multicomponent)	
+ hydrochloric acid	E253, 263
+ strontium hydroxide	E253, 263
Strontium hydrosulfide (aqueous)	
+ strontium hydroxide	E253, 266, 267
Strontium hydroxide	
+ water	E248-E255, 256-260
Strontium hydroxide (aqueous)	
+ ammonia	E290, 340-342
+ 1,2-ethanediol	E254, 272
+ ethanol	E254, 270-272
+ N-ethylethanamine	E254, 272
+ D-mannitol	E254, 272
+ methanol	E254, 272
+ 2-methyl-2-butanol	E254, 272
+ nitric acid, strontium salt	E253, 269
+ nitrous acid, strontium salt	188, 268
+ 1,1'-oxybisethane	E254, 272
+ 1,2,3-propanetriol	E254, 272
+ 1-propanol	E254, 272
+ 2-propanone	E254, 272
+ pyridine	E254, 272
+ strontium bromide	E253, 264
+ strontium chloride	E253, 261, 262

Strontium hydroxide (aqueous)	
+ strontium hydrosulfide	E253, 266, 267
+ strontium iodide	E253, 265
+ urea	E254, 272
Strontium hydroxide (multicomponent)	
+ hydrochloric acid	E253, 263
+ strontium chloride	E253, 263
Strontium iodide (aqueous)	
+ strontium hydroxide	E253, 265
Sucrose (aqueous)	
+ barium hydroxide	E290, 340-342
+ calcium hydroxide	E120, E122, 236-242
+ strontium hydroxide	E253, 275-283
Sucrose (multicomponent)	
+ calcium chloride	E120, E122, 245, 246
+ calcium hydroxide	E120, E122, 243-246
+ calcium oxide	E120, E122, 243, 244
+ sodium chloride	E120, E122, 245, 246
Sulfuric acid, ammonium salt (multicomponent)	
+ ammonia	E52, 93
+ magnesium hydroxide	E52, 93
+ sulfuric acid, magnesium salt	E52, 93
Sulfuric acid, beryllium salt (aqueous)	
+ beryllium hydroxide	E6, 29
Sulfuric acid, beryllium salt (multicomponent)	
+ beryllium hydroxide	E6, 30-32
+ potassium hydroxide	E6, 32
+ sodium hydroxide	E6, 30, 31
Sulfuric acid, calcium salt (aqueous)	
+ calcium hydroxide	E120, 185
Sulfuric acid, calcium salt (multicomponent)	
+ potassium hydroxide	E120, 186, 187
+ sodium hydroxide	E120, 186, 187
Sulfuric acid, magnesium salt (aqueous)	
+ magnesium hydroxide	E59, 92
Sulfuric acid, magnesium salt (multicomponent)	
+ ammonia	E52, 93
+ magnesium hydroxide	E52, 93
+ sulfuric acid, ammonium salt	E52, 93
Sulfuric acid, sodium salt (aqueous)	
+ magnesium hydroxide	E50, E51, E53, E54, E56-E58, 105, 109
Thiocyanic acid, ammonium salt (multicomponent)	
+ ammonia	E52, 94
+ magnesium hydroxide	E52, 94
+ thiocyanic acid, magnesium salt	E52, 94
Thiocyanic acid, barium salt (aqueous)	
+ barium hydroxide	E290, 324
Thiocyanic acid, magnesium salt (multicomponent)	
+ ammonia	E52, 94
+ magnesium hydroxide	E52, 94
+ thiocyanic acid, ammonium salt	E52, 94
Urea (aqueous)	
+ strontium hydroxide	E254, 272

REGISTRY NUMBER INDEX

Pages preceded by E refer to evaluation texts whereas those not preceded by E refer to compiled tables.

SOLUBILITY DATA SERIES

- Volume 1 H. L. Clever, *Helium and Neon*
- Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
- Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
- Volume 4 H. L. Clever, *Argon*
- Volume 5/6 C. L. Young, *Hydrogen and Deuterium*
- Volume 7 R. Battino, *Oxygen and Ozone*
- Volume 8 C. L. Young, *Oxides of Nitrogen*
- Volume 9 W. Hayduk, *Ethane*
- Volume 10 R. Battino, *Nitrogen and Air*
- Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline Earth Metal and Ammonium Halides, Amide Solvents*
- Volume 12 C. L. Young, *Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides*
- Volume 13 S. Siekierski, T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Nitrates*
- Volume 14 H. Miyamoto, M. Salomon and H. L. Clever, *Alkaline Earth Metal Halates*
- Volume 15 A. F. M. Barton, *Alcohols with Water*
- Volume 16/17 E. Tomlinson and A. Regosz, *Antibiotics: 1, β -Lactam Antibiotics*
- Volume 18 O. Popovych, *Tetraphenylborates*
- Volume 19 C. L. Young, *Cumulative Index: Volumes 1-18*
- Volume 20 A. L. Horvath and F. W. Getzen, *Halogenated Benzenes, Toluenes and Phenols with Water*
- Volume 21 C. L. Young and P. G. T. Fogg, *Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents*
- Volume 22 T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents*
- Volume 23 T. P. Dirkse, *Copper, Silver, Gold and Zinc, Cadmium, Mercury Oxides and Hydroxides*
- Volume 24 W. Hayduk, *Propane, Butane and 2-Methylpropane*
- Volume 25 C. Hirayama, Z. Galus and C. Guminski, *Metals in Mercury*
- Volume 26 M. R. Masson, H. D. Lutz and B. Engelen, *Sulfites, Selenites and Tellurites*
- Volume 27/28 H. L. Clever and C. L. Young, *Methane*
- Volume 29 H. L. Clever, *Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements*
- Volume 30 H. Miyamoto and M. Salomon, *Alkali Metal Halates, Ammonium Iodate and Iodic Acid*
- Volume 31 J. Eysseltová and T. P. Dirkse, *Alkali Metal Orthophosphates*

- Volume 32 P. G. T. Fogg and C. L. Young, *Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide*
- Volume 33 P. Franzosini, *Molten Alkali Metal Alkanoates*
- Volume 34 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part I: Non-cyclic Substituents*
- Volume 35 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part II: 5-Membered Heterocyclic Substituents*
- Volume 36 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part III: 6-Membered Heterocyclic Substituents and Miscellaneous Systems*
- Volume 37 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part I: Hydrocarbons C₅ to C₇*
- Volume 38 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part II: Hydrocarbons C₈ to C₃₆*
- Volume 39 C. L. Young, *Cumulative Index: Volumes 20-38*
- Volume 40 J. Hala, *Halides, Oxyhalides and Salts of Halogen Complexes of Titanium, Zirconium, Hafnium, Vanadium, Niobium and Tantalum*
- Volume 41 C.-Y. Chan, I. N. Lepeshkov and K. H. Khoo, *Alkaline Earth Metal Perchlorates*
- Volume 42 P. G. T. Fogg and W. Gerrard, *Hydrogen Halides in Non-aqueous Solvents*
- Volume 43 R. W. Cargill, *Carbon Monoxide*
- Volume 44 H. Miyamoto, E. M. Woolley and M. Salomon, *Copper and Silver Halates*
- Volume 45/46 R. P. T. Tomkins and N. P. Bansal, *Gases in Molten Salts*
- Volume 47 R. Cohen-Adad and J. W. Lorimer, *Alkali Metal and Ammonium Chlorides in Water and Heavy Water (Binary Systems)*
- Volume 48 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part I: Esters 2-C to 6-C*
- Volume 49 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part II: Esters 7-C to 32-C*
- Volume 50 P. G. T. Fogg, *Carbon Dioxide in Non-aqueous Solvents at Pressures less than 200 kPa*
- Volume 51 J. G. Osteryoung, M. M. Schreiner, C. Guminski and Z. Galus, *Intermetallic Compounds in Mercury*
- Volume 52 I. Lambert and H. L. Clever, *Alkaline Earth Hydroxides in Water and Aqueous Solutions*
