A further 60-80 volumes are in progress to complete the Series.

NOTICE TO READERS

Dear Reader

If your library is not already a standing-order customer or subscriber to the Solubility Data Series, may we recommend that you place a standing order or subscription order to receive immediately upon publication all new volumes published in this valuable series. Should you find that these volumes no longer serve your needs, your order can be cancelled at any time without notice.

Robert Maxwell
Publisher at Pergamon Press
FOREWORD

If the knowledge is undigested or simply wrong, more is not better.

How to communicate and disseminate numerical data effectively in chemical science and technology has been a problem of serious and growing concern to IUPAC, the International Union of Pure and Applied Chemistry, for the last two decades. The steadily expanding volume of numerical information, the formulation of new interdisciplinary areas in which chemistry is a partner, and the links between these and existing traditional subdisciplines in chemistry, along with an increasing number of users, have been considered as urgent aspects of the information problem in general, and of the numerical data problem in particular.

Among the several numerical data projects initiated and operated by various IUPAC commissions, the Solubility Data Project is probably one of the most ambitious ones. It is concerned with preparing a comprehensive critical compilation of data on solubilities in all physical systems, of gases, liquids and solids. Both the basic and applied branches of almost all scientific disciplines require a knowledge of solubilities as a function of solvent, temperature and pressure. Solubility data are basic to the fundamental understanding of processes relevant to agronomy, biology, chemistry, geology and oceanography, medicine and pharmacology, and metallurgy and materials science. Knowledge of solubility is very frequently of great importance to such diverse practical applications as drug dosage and drug solubility in biological fluids, anesthesiology, corrosion by dissolution of metals, properties of glasses, ceramics, concretes and coatings, phase relations in the formation of minerals and alloys, the deposits of minerals and radioactive fission produces from ocean waters, the composition of ground waters, and the requirements of oxygen and other gases in life support systems.

The widespread relevance of solubility data to many branches and disciplines of science, medicine, technology and engineering, and the difficulty of recovering solubility data from the literature, lead to the proliferation of published data in an ever increasing number of scientific and technical primary sources. The sheer volume of data has overcome the capacity of the classical secondary and tertiary services to respond effectively.

While the proportion of secondary services of the review article type is generally increasing due to the rapid growth of all forms of primary literature, the review articles become more limited in scope, more specialized. The disturbing phenomenon is that in some disciplines, certainly in chemistry, authors are reluctant to treat even those limited-in-scope reviews exhaustively. There is a trend to preselect the literature, sometimes under the pretext of reducing it to manageable size. The crucial problem with such preselection - as far as numerical data are concerned - is that there is no indication as to whether the material was excluded by design or by a less than thorough literature search. We are equally concerned that most current secondary sources, critical in character as they may be, give scant attention to numerical data.

On the other hand, tertiary sources - handbooks, reference books, and other tabulated and graphical compilations - as they exist today, are comprehensive but, as a rule, uncritical. They usually attempt to cover whole disciplines, thus obviously are superficial in treatment. Since they command a wide market, we believe that their service to advancement of science is at least questionable. Additionallly, the change which is taking place in the generation of new and diversified numerical data, and the rate at which this is done, is not reflected in an increased third-level service. The emergence of new tertiary literature sources does not parallel the shift that has occurred in the primary literature.

With the status of current secondary and tertiary services being as briefly stated above, the innovative approach of the Solubility Data Project is that its compilation and critical evaluation work involve consolidation and reprocessing services when both activities are based on intellectual and scholarly reworking of information from primary sources. It comprises compact compilation, rationalization and simplification, and the fitting of isolated numerical data into a critically evaluated general framework.
The Solubility Data Project has developed a mechanism which involves a number of innovations in exploiting the literature fully, and which contains new elements of a more imaginative approach for transfer of reliable information from primary to secondary/tertiary sources. The fundamental trend of the Solubility Data Project is toward integration of secondary and tertiary services with the objective of producing in-depth critical analyses and evaluation which are characteristic to secondary services, in a scope as broad as conventional tertiary services.

Fundamental to the philosophy of the project is the recognition that the basic element of strength is the active participation of career scientists in it. Consolidating primary data, producing a truly critically-evaluated set of numerical data, and synthesizing data in a meaningful relationship are demands considered worthy of the efforts of top scientists. Career scientists, who themselves contribute to science by their involvement in active scientific research, are the backbone of the project. The scholarly work is commissioned to recognized authorities, involving a process of careful selection in the best tradition of IUPAC. This selection in turn is the key to the quality of the output. These top experts are expected to view their specific topics dispassionately, paying equal attention to their own contributions and to those of their peers. They digest literature data into a coherent story by weeding out what is wrong from what is believed to be right. To fulfill this task, the evaluator must cover all relevant open literature. No reference is excluded by design and every effort is made to detect every bit of relevant primary source. Poor quality or wrong data are mentioned and explicitly disqualified as such. In fact, it is only when the reliable data are presented alongside the unreliable data that proper justice can be done. The user is bound to have incomparably more confidence in a succinct evaluative commentary and a comprehensive review with a complete bibliography to both good and poor data.

It is the standard practice that any given solute-solvent system consists of two essential parts: I. Critical Evaluation and Recommended Values, and II. Compiled Data Sheets.

The Critical Evaluation part gives the following information:
(i) a verbal text of evaluation which discusses the numerical solubility information appearing in the primary sources located in the literature. The evaluation text concerns primarily the quality of data after consideration of the purity of the materials and their characterization, the experimental method employed and the uncertainties in control of physical parameters, the reproducibility of the data, the agreement of the worker's results on accepted test systems with standard values, and finally, the fitting of data, with suitable statistical tests, to mathematical functions;
(ii) a set of recommended numerical data. Whenever possible, the set of recommended data includes weighted average and standard deviations, and a set of smoothing equations derived from the experimental data endorsed by the evaluator;
(iii) a graphical plot of recommended data.

The compilation part consists of data sheets of the best experimental data in the primary literature. Generally speaking, such independent data sheets are given only to the best and endorsed data covering the known range of experimental parameters. Data sheets based on primary sources where the data are of a lower precision are given only when no better data are available. Experimental data with a precision poorer than considered acceptable are reproduced in the form of data sheets when they are the only known data for a particular system. Such data are considered to be still suitable for some applications, and their presence in the compilation should alert researchers to areas that need more work.

The typical data sheet carries the following information:
(i) components - definition of the system - their names, formulas and Chemical Abstracts registry numbers;
(ii) reference to the primary source where the numerical information is reported. In cases when the primary source is a less common periodical or a report document, published though of limited availability, abstract references are also given;
(iii) experimental variables;
(iv) identification of the compiler;
(v) experimental values as they appear in the primary source. Whenever available, the data may be given both in tabular and graphical form. If auxiliary information is available, the experimental data are converted also to SI units by the compiler.
Under the general heading of Auxiliary Information, the essential experimental details are summarized:

(vi) experimental method used for the generation of data;
(vii) type of apparatus and procedure employed;
(viii) source and purity of materials;
(ix) estimated error;
(x) references relevant to the generation of experimental data as cited in the primary source.

This new approach to numerical data presentation, developed during our four years of existence, has been strongly influenced by the diversity of background of those whom we are supposed to serve. We thus deemed it right to preface the evaluation/compilation sheets in each volume with a detailed discussion of the principles of the accurate determination of relevant solubility data and related thermodynamic information.

Finally, the role of education is more than corollary to the efforts we are seeking. The scientific standards advocated here are necessary to strengthen science and technology, and should be regarded as a major effort in the training and formation of the next generation of scientists and engineers. Specifically, we believe that there is going to be an impact of our project on scientific-communication practices. The quality of consolidation adopted by this program offers down-to-earth guidelines, concrete examples which are bound to make primary publication services more responsive than ever before to the needs of users. The self-regulatory message to scientists of 15 years ago to refrain from unnecessary publication has not achieved much. The literature is still, in 1979, cluttered with poor-quality articles. The Weinberg report (in "Reader in Science Information", Eds. J. Sherrod and A. Hodina, Microcard Editions Books, Indian Head, Inc., 1973, p. 292) states that "admonition to authors to restrain themselves from premature, unnecessary publication can have little effect unless the climate of the entire technical and scholarly community encourages restraint..." We think that projects of this kind translate the climate into operational terms by exerting pressure on authors to avoid submitting low-grade material. The type of our output, we hope, will encourage attention to quality as authors will increasingly realize that their work will not be suited for permanent retrievability unless it meets the standards adopted in this project. It should help to dispel confusion in the minds of many authors of what represents a permanently useful bit of information of an archival value, and what does not.

If we succeed in that aim, even partially, we have then done our share in protecting the scientific community from unwanted and irrelevant, wrong numerical information.

A. S. Kertes
PREFACE TO THE VOLUME

This volume surveys the solubility data available in the literature of the halides and pseudohalides of the alkali, alkali earth and ammonium ions in the six simple amides, formamide, N-methylformamide, N,N-dimethylformamide, acetamide, N-methylacetamide and N,N-dimethylacetamide.

These solvents are of both theoretical and practical interest, primarily because of their ability to dissolve significant quantities of electrolytes. With the exception of acetamide, the amides are liquid at room temperature and have liquid ranges of over 175°. All the solvent molecules are characterised by large dipole moments and, apart from the two di-N-substituted forms, have exceptionally high dielectric constants. There have been many physicochemical studies of electrolytic solutions in the amides. These have concentrated mainly on ionic solvation and mobility, thermodynamics and electrochemistry. Despite such investigations few comprehensive studies of solubility have been reported. The number of reliable data available is further restricted by the fact that many of these measurements were not undertaken with sufficient care in the use of procedures for purifying salt and/or solvent, in controlling the temperature and in selecting the most suitable analytical methods. In evaluating the various systems, particular attention was directed (i) to the techniques and procedures used in the purification of solvents and salts, and (ii) to the length of time allowed to ensure saturation and to the methods used to detect that equilibrium had been established.

All the solvents, when pure, are fairly stable - the acetamide series being more so than the formamides. They are, however, generally sensitive to heat, light and water, and to obtain them in reasonably pure state requires elaborate procedures and particular care. Decomposition of the formamides is particularly susceptible to traces of water impurity and is both acid- and base- catalysed. It is well known that a number of the salts investigated, such as lithium and alkali earth halides also require special methods in order to obtain them in a pure, dry state. A further problem that may arise when traces of water are present is preferential ionic solvation by water which may in turn give rise to overestimates of the solubility.

The following points have governed the general nature of this volume:

(i) The majority of quantitative solubility studies have been of fairly soluble salts. Since activity coefficients were generally not available for such concentrated solutions, few thermodynamic solubility products have been reported.

(ii) Only rarely was an analysis of the solid phase carried out and therefore no attempt has been made to provide a general discussion of the solid-liquid equilibria in this volume. Indeed many of the solubilities reported may have been considerably affected by undetected solvate formation.

(iii) The absence of reliable density data has not allowed the conversion of results reported in molar units into molal units and vice versa (in accordance with the recommendations and guidelines of the Solubility Data Project directorate). This has had the effect of reducing the possibilities of intercomparison for the evaluation and recommendation of solubility values.
(iv) So far as we are aware, the entire literature has been covered in this survey. In a few cases it has not been possible to obtain copies of original papers published in the U.S.S.R. and data from these sources have not been compiled nor evaluated.

(v) It was not generally possible to find replicate data within a single study so that an independent analysis of the error could be undertaken. In a number of cases the authors' estimated error is given. In others approximate methods have been used to estimate the error, such as by the scatter of values of the logarithm of solubility when plotted against the reciprocal of the absolute temperature. Where clearly no serious attempt was made to obtain satisfactory anhydrous conditions, we have considered that an error, generally estimated as of the order of a few per cent, was likely. An error of similar magnitude was also attributed to data obtained after equilibration times considered too short to have allowed a saturation equilibrium to have been achieved. (In general dissolution is a particularly slow process in the amide systems, especially at low temperature).

(vi) All the above considerations were taken into account in the selection of the most reliable data for the solubility values. In a number of systems, however, no data could be recommended with confidence and only tentative values, very approximate estimates or even no values are given. In reporting the experimental methods and in the compilations, the units used by the original investigators are usually retained. In the critical evaluations the values have been converted to S.I. units.

Finally we would like to acknowledge all those who have contributed to the final version of this volume. In particular we thank C.M. Criss, J.W. Lorimer, G.H. Nancollas, M. Salomon and P.G. Sears for their valuable and helpful comments and suggestions.

C. A. Vincent
INTRODUCTION TO THE SOLUBILITY OF
SOLIDS IN LIQUIDS

Nature of the Project

The Solubility Data Project (SDP) has as its aim a comprehensive search of the literature for solubilities of gases, liquids, and solids in liquids or solids. Data of suitable precision are compiled on data sheets in a uniform format. The data for each system are evaluated, and where data from different sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

This series of volumes includes solubilities of solids of all types in liquids of all types.

Definitions

A mixture (1,2) describes a gaseous, liquid, or solid phase containing more than one substance, when the substances are all treated in the same way.

A solution (1,2) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the solvent and may itself be a mixture, is treated differently than the other substances, which are called solutes. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a dilute solution.

The solubility of a substance B is the relative proportion of B (or a substance related chemically to B) in a mixture which is saturated with respect to solid B at a specified temperature and pressure. Saturated implies the existence of equilibrium with respect to the processes of dissolution and precipitation; the equilibrium may be stable or metastable. The solubility of a metastable substance is usually greater than that of the corresponding stable substance. (Strictly speaking, it is the activity of the metastable substance that is greater.) Care must be taken to distinguish true metastability from supersaturation, where equilibrium does not exist.

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the quantities used as measures of solubility and in the reference states used for definition of activities and activity coefficients.

The qualifying phrase "substance related chemically to B" requires comment. The composition of the saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components. Thus, the solubility of a salt hydrate in water is usually given as the relative proportion of anhydrous salt in solution, rather than the relative proportions of hydrated salt and water.

Quantities Used as Measures of Solubility

1. Mole fraction of substance B, \( x_B \):

\[
x_B = \frac{n_B}{\sum_{i=1}^{c} n_i}
\]

where \( n_i \) is the amount of substance of substance \( i \), and \( c \) is the number of distinct substances present (often the number of thermodynamic components in the system). Mole per cent of B is 100 \( x_B \).

2. Mass fraction of substance B, \( w_B \):

\[
w_B = \frac{m'_B}{\sum_{i=1}^{c} m'_i}
\]

where \( m'_i \) is the mass of substance \( i \). Mass per cent of B is 100 \( w_B \). The equivalent terms weight fraction and weight per cent are not used.

3. Solute mole (mass) fraction of solute B (3,4):

\[
x_{S,B} = \frac{n_B}{\sum_{i=1}^{c'} n_i} = \frac{x_B}{\sum_{i=1}^{c'} x_i}
\]

where the summation is over the solutes only. For the solvent A, \( x_{S,A} = x_A \). These quantities are called Jünecke mole (mass) fractions in many papers.
4. **Molality** of solute B (1,2) in a solvent A:

\[ m_B = \frac{n_B}{n_A M_A} \]  
SI base units: mol kg\(^{-1}\)  

(4)

where \( M_A \) is the molar mass of the solvent.

5. **Concentration** of solute B (1,2) in a solution of volume \( V \):

\[ c_B = \frac{[B]}{V} = \frac{n_B}{V} \]  
SI base units: mol m\(^{-3}\)  

(5)

The terms molarity and molar are not used.

Mole and mass fractions are appropriate to either the mixture or the solution points of view. The other quantities are appropriate to the solution point of view only. In addition of these quantities, the following are useful in conversions between concentrations and other quantities.

6. **Density**: \( \rho = \frac{m}{V} \)  
SI base units: kg m\(^{-3}\)  

(6)

7. **Relative density**: \( d \), the ratio of the density of a mixture to the density of a reference substance under conditions which must be specified for both (1). The symbol \( d_f \), will be used for the density of a mixture at 0°C, 1 atm divided by the density of water at 0°C, 1 atm.

Other quantities will be defined in the prefaces to individual volumes or on specific data sheets.

**Thermodynamics of Solubility**

The principal aims of the Solubility Data Project are the tabulation and evaluation of: (a) solubilities as defined above; (b) the nature of the saturating solid phase. Thermodynamic analysis of solubility phenomena has two aims: (a) to provide a rational basis for the construction of functions to represent solubility data; (b) to enable thermodynamic quantities to be extracted from solubility data. Both these aims are difficult to achieve in many cases because of a lack of experimental or theoretical information concerning activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve critical evaluation of a large body of data that is not directly relevant to solubility. The following discussion is an outline of the principal thermodynamic relations encountered in discussions of solubility. For more extensive discussions and references, see books on thermodynamics, e.g., (5-10).

**Activity Coefficients** (1)

(a) **Mixtures.** The activity coefficient \( f_B \) of a substance B is given by

\[ \frac{RT \ln(f_B x_B)}{\mu_B - \mu_B^*} = \frac{1}{x_B + 1} \]  
(7)

where \( \mu_B \) is the chemical potential, and \( \mu_B^* \) is the chemical potential of pure B at the same temperature and pressure. For any substance B in the mixture,

\[ \lim_{x_B \to 0} f_B = 1 \]  
(8)

(b) **Solutions.**

(i) **Solute substance, B.** The molal activity coefficient \( \gamma_B \) is given by

\[ \frac{RT \ln(\gamma_B m_B)}{\mu_B - (\mu_B - RT \ln m_B)^\infty} = x_B \]  
(9)

where the superscript \( \infty \) indicates an infinitely dilute solution. For any solute B,

\[ \gamma_B^\infty = 1 \]  
(10)

Activity coefficients \( \gamma_B \) connected with concentration \( c_B \), and \( f_{x_B} \) (called the **rational activity coefficient**) connected with mole fraction \( x_B \) are defined in analogous ways. The relations among them are (1,9):

\[ \gamma_B = x_A f_{x_B} = v_A^* (1 - \Sigma c_s) \gamma_B \]  
(11)

or
\[ f_{x,B} = (1 + M_A \Sigma_m) \gamma_B = V_A^* y_B / V_m \] (12)

or

\[ \gamma_B^{m_B} = \gamma_\pm^{m_B} v_\pm^{Q} \] (14)

where \( v = v_+ + v_- \), \( Q = (v_+ v_+^v v_-^v) l/v \), and \( \gamma_\pm \) is the mean ionic molal activity coefficient. A similar relation holds for the concentration activity \( \gamma_B^{c_B} \). For the mol fractional activity,

\[ f_{x,B} x_B = v_+ v_- f_\pm x_\pm^v \] (15)

The quantities \( x_+ \) and \( x_- \) are the ionic mole fractions \( \xi(9) \), which for a single solute are

\[ x_+ = v_+ x_B / [1 + (v-1)x_B] ; \quad x_- = v_- x_B / [1 + (v-1)x_B] \] (16)

(ii) Solvent, \( A \):

The osmotic coefficient, \( \phi \), of a solvent substance \( A \) is defined as (1):

\[ \phi = (\mu_A^* - \mu_A) / RT M_A \Sigma_m \] (17)

where \( \mu_A^* \) is the chemical potential of the pure solvent.

The national osmotic coefficient, \( \phi_N \), is defined as (1):

\[ \phi_N = (\mu_A - \mu_A^*) / RT \ln x_A = \phi / n_A \Sigma_m / \ln (1 + \Sigma_m x_A) \] (18)

The activity, \( a_A \), or the activity coefficient \( f_A \) is often used for the solvent rather than the osmotic coefficient. The activity coefficient is defined relative to pure \( A \), just as for a mixture.

The Liquid Phase

A general thermodynamic differential equation which gives solubility as a function of temperature, pressure and composition can be derived. The approach is that of Kirkwood and Oppenheim (7). Consider a solid mixture containing \( c' \) thermodynamic components i. The Gibbs-Duhem equation for this mixture is:

\[ \sum_{i=1}^{c'} x_i' (S_i' dT - V_i' dp + d\mu_i) = 0 \] (19)

A liquid mixture in equilibrium with this solid phase contains \( c \) thermodynamic components i, where, usually, \( c > c' \). The Gibbs-Duhem equation for the liquid mixture is:

\[ \sum_{i=1}^{c'} x_i (S_i dT - V_i dp + d\mu_i) + \sum_{i=c'+1}^{c} x_i (S_i dT - V_i dp + d\mu_i) = 0 \] (20)

Eliminate \( d\mu_i \) by multiplying (19) by \( x_i \) and (20) \( x_i' \). After some algebra, and use of:

\[ d\mu = \sum_{j=2}^{c'} G_{ij} dx_j - S_i dT + V_i dp \] (21)

where (7)

\[ G_{ij} = \left( \frac{\partial \mu_i}{\partial x_j} \right)_{T,P} x_i x_j \] (22)

it is found that

\[ \sum_{i=2}^{c'} \sum_{j=2}^{c'} (x_i' - x_i) G_{ij} dx_j = (x_i' / x_i) \sum_{i=2}^{c'} \sum_{j=2}^{c'} x_i G_{ij} dx_j \]

\[ = \sum_{i=1}^{c'} x_i' (H_i - H_i') dT / T - \sum_{i=1}^{c'} x_i' (V_i - V_i') dp \] (23)
where
\[ H_1 - H_1' = T(S_1 - S_1') \]  
(24)
is the enthalpy of transfer of component i from the solid to the liquid phase, at a given temperature, pressure and composition, and \( H_1, S_1, V_i \) are the partial molar enthalpy, entropy, and volume of component i. Several special cases (all with pressure held constant) will be considered. Other cases will appear in individual evaluations.

(a) Solubility as a function of temperature.
Consider a binary solid compound \( A_nB \) in a single solvent \( A \). There is no fundamental thermodynamic distinction between a binary compound of \( A \) and \( B \) which dissociates completely or partially on melting and a solid mixture of \( A \) and \( B \); the binary compound can be regarded as a solid mixture of constant composition. Thus, with \( c = 2, c' = 1, \alpha_A' = n/(n+1), \alpha_B' = 1/(n+1), \) eqn (23) becomes
\[ \left( 1/x_B - n/x_A \right) \left( 1 + \left( \frac{\alpha_B'}{\alpha_A'} \right) \right) \frac{d\ln f_B}{T_P} = \left( nH_A + H_{AB} - nH_A' \right) dT/RT^2 \]  
(25)
where the mole fractional activity coefficient has been introduced. If the mixture is a non-electrolyte, and the activity coefficients are given by the expression for a simple mixture (6):
\[ \ln f_B = wx_A^2 \]  
(26)
then it can be shown that, if \( w \) is independent of temperature, eqn (25) can be integrated (cf. (5), Chap. XXIII, sect. 5). The enthalpy term becomes
\[ \frac{nH_A + H_{AB} - nH_A'}{T_P} = \Delta H_{AB} + w(nx_B^2 + x_A^2) \]  
(27)
where \( \Delta H_{AB} \) is the enthalpy of melting and dissociation of one mole of pure solid \( A_nB \), and \( H_A', H_B' \) are the molar enthalpies of pure liquid \( A \) and \( B \).

The differential equation becomes
\[ \frac{dx_B}{dT} = \frac{\Delta H_{AB}}{RT} \]  
(28)
Integration from \( x_B,T \) to \( x_B = 1/(1+n) \), \( T = T^* \), the melting point of the pure binary compound, gives:
\[ \ln(x_B^{-1}x_B^n) = -\Delta H_{AB} (\frac{1}{T}) - w \left( \frac{x_A^2 + nx_B^2}{T} \right) \]  
(29)
where \( \Delta C_p^* \) is the change in molar heat capacity accompanying fusion plus decomposition of the compound at temperature \( T^* \), (assumed here to be independent of temperature and composition), and \( \Delta H_{AB} \) is the corresponding change in enthalpy at \( T = T^* \). Equation (29) has the general form
\[ \ln(x_B^{-1}x_B^n) = A_1 + A_2/T + A_3\ln T + A_4(x_A^2 + nx_B^2)/T \]  
(30)
If the solid contains only component \( B, n = 0 \) in eqn (29) and (30).

If the infinite dilution standard state is used in eqn (25), eqn (26) becomes
\[ RT \ln f_B = w(x_A^2 - 1) \]  
(31)and (27) becomes
\[ nH_A + H_{AB} = \frac{nH_A^\infty + H_{AB}^\infty - H_A^* + (H_B - H_B^\infty)}{T_P} = \Delta H_{AB}^\infty + w(nx_B^2 + x_A^2 - 1) \]  
(32)
where the first term, \( \Delta H_{AB}^\infty \), is the enthalpy of melting and dissociation of solid compound \( A_nB \) to the infinitely dilute state of solute \( B \) in solvent \( A \); \( H_B^* \) is the partial molar enthalpy of the solute at infinite dilution. Clearly, the integral of eqn (25) will have the same form as eqn (29), with \( \Delta H_{AB}(T^*), \Delta C_p^* \) replacing \( \Delta H_{AB} \) and \( \Delta C_p^* \) and \( x_A^2 - 1 \) replacing \( x_A^2 \) in the last term.
If the liquid phase is an aqueous electrolyte solution, and the solid is a salt hydrate, the above treatment needs slight modification. Using rational mean activity coefficients, eqn (25) becomes

\[ \text{RV}(1/x_B-n/x_A)(1+(a_{nf}/a_n)\text{d}x_B/(1+(v-1)x_B)) \]

\[ = \left( \Delta H_{AB}^{\infty} + n(H_A-H_A^*) + (H_B-H_B^*) \right) d(1/T) \]

If the terms involving activity coefficients and partial molar enthalpies are negligible, then integration gives (cf. (11)):

\[ \ln\left( \frac{1-n}{1+(v-1)x_B^{-n/y}} \right) = \ln\left( \frac{n}{(n+y)(1+y)} \right) - \left( \frac{\Delta H_{AB}^{\infty}(T^*)-T^*\Delta C^*}{R} \right) \left( \frac{1}{T} - \frac{1}{T^*} \right) + \frac{2\ln(T/T^*)}{R} \]

A similar equation (with \( v=2 \) and without the heat capacity terms) has been used to fit solubility data for some MOH=H₂O systems, where M is an alkali metal; the enthalpy values obtained agreed well with known values (11). In many cases, data on activity coefficients (9) and partial molar enthalpies (8,10) in concentrated solution indicate that the terms involving these quantities are not negligible, although they may remain roughly constant along the solubility temperature curve.

The above analysis shows clearly that a rational thermodynamic basis exists for functional representation of solubility-temperature curves in two-component systems, but may be difficult to apply because of lack of experimental or theoretical knowledge of activity coefficients and partial molar enthalpies. Other phenomena which are related ultimately to the stoichiometric activity coefficients and which complicate interpretation include ion pairing, formation of complex ions, and hydrolysis. Similar considerations hold for the variation of solubility with pressure, except that the effects are relatively smaller at the pressures used in many investigations of solubility (5).

(b) Solubility as a function of composition.

At constant temperature and pressure, the chemical potential of a saturating solid phase is constant:

\[ \mu_A = \mu_A^*(\text{sln}) = n\mu_A^* + \mu_B \]

\[ = (nu_A^* + v_+\mu_+^* + v_-\mu_-^*) + nRT \ln\mu_A \]

\[ + vRT \ln y_{+m_-}Q_{+} \]

for a salt hydrate \( A_nB \) which dissociates to water, (A), and a salt, B, one mole of which ionizes to give \( v_+ \) cations and \( v_- \) anions in a solution in which other substances (ionized or not) may be present. If the saturated solution is sufficiently dilute, \( f_A = x_A = 1 \), and the quantity \( K_{S0} \) in

\[ \Delta G^{\infty} = \mu_+^* + \mu_-^* + n\mu_A^* - \mu_{AB}^* \]

\[ = -RT \ln K_{S0} \]

\[ = -RT \ln Q y_{+m_-}v_+v_- \]

is called the solubility product of the salt. (It should be noted that it is not customary to extend this definition to hydrated salts, but there is no reason why they should be excluded.) Values of the solubility product are often given on mole fraction or concentration scales. In dilute solutions, the theoretical behaviour of the activity coefficients as a function of ionic strength is often sufficiently well known that reliable extrapolations to infinite dilution can be made, and values of \( K_{S0} \) can be determined. In more concentrated solutions, the same problems with activity coefficients that were outlined in the section on variation of solubility with temperature still occur. If these complications do not arise, the solubility of a hydrate salt \( C v_+v_-nH_2O \) in the presence of other solutes is given by eqn (36) as

\[ v \ln(m_B/m_B(0)) = -vln(y_{+}/y_{+}(0)) - n \ln(a_{H_2O}/a_{H_2O}(0)) \]

where \( a_{H_2O} \) is the activity of water in the saturated solution, \( m_B \) is the molality of the salt in the saturated solution, and (0) indicates absence of other solutes. Similar considerations hold for non-electrolytes.
The definition of solubility permits the occurrence of a single solid phase which may be a pure anhydrous compound, a salt hydrate, a non-stoichiometric compound, or a solid mixture (or solid solution, or "mixed crystals"), and may be stable or metastable. As well, any number of solid phases consistent with the requirements of the phase rule may be present. Metastable solid phases are of widespread occurrence, and may appear as polymorphic (or allotropic) forms or crystal solvates whose rate of transition to more stable forms is very slow. Surface heterogeneity may also give rise to metastability, either when one solid precipitates on the surface of another, or if the size of the solid particles is sufficiently small that surface effects become important. In either case, the solid is not in stable equilibrium with the solution. The stability of a solid may also be affected by the atmosphere in which the system is equilibrated.

Many of these phenomena require very careful, and often prolonged, equilibration for their investigation and elimination. A very general analytical method, the "wet residues" method of Schreinemakers (12) (see a text on physical chemistry) is usually used to investigate the composition of solid phases in equilibrium with salt solutions. In principle, the same method can be used with systems of other types. Many other techniques for examination of solids, in particular X-ray, optical, and thermal analysis methods, are used in conjunction with chemical analyses (including the wet residues method).

COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A brief description of the data sheets has been given in the FOREWORD; additional explanation is given below.

Guide to the Compilations

The format used for the compilations is, for the most part, self-explanatory. The details presented below are those which are not found in the FOREWORD or which are not self-evident.

Components. Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The formula is given either in terms of the IUPAC or Hill (13) system and the choice of formula is governed by what is usual for most current users: i.e. IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered according to:

(a) saturating components;
(b) non-saturating components in alphanumerical order;
(c) solvents in alphanumerical order.

The saturating components are arranged in order according to a 18-column, 2-row periodic table:

Columns 1,2: H, groups IA, IIA;
3,12: transition elements (groups IIIB to VIIB, group VIII, groups IB, IIB);
13-18: groups IIIA-VIIA, noble gases.

Row 1: Ce to Lu;
Row 2: Th to the end of the known elements, in order of atomic number.

Salt hydrates are generally not considered to be saturating components since most solubilities are expressed in terms of the anhydrous salt. The existence of hydrates or solvates is carefully noted in the texts, and CA Registry Numbers are given where available, usually in the critical evaluation. Mineralogical names are also quoted, along with their CA Registry Numbers, again usually in the critical evaluation.

Original Measurements. References are abbreviated in the forms given by Chemical Abstracts Service Source Index (CASSI). Names originally in other than Roman alphabets are given as transliterated by Chemical Abstracts.

Experimental Values. Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm⁻³ for molar; etc. Both mass and molar values are given. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the other type of value (e.g., mole per cent) from computer calculations based on 1976 atomic weights (14). Errors in calculations and fitting equations in original papers have been noted and corrected, by computer calculations where necessary.

Method, Source and Purity of Materials. Abbreviations used in Chemical Abstracts are often used here to save space.

Estimated Error. If these data were omitted by the original authors, and if relevant information is available, the compilers have attempted to
estimate errors from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on the papers by Ku and Eisenhart (15).

Comment and/or Additional Data. Many compilations include this section which provides short comments relevant to the general nature of the work or additional experimental and thermodynamic data which are judged by the compiler to be of value to the reader.

References. See the above description for Original Measurements.

Guide to the Evaluations

The evaluator's task is to check whether the compiled data are correct, to assess the reliability and quality of the data, to estimate errors where necessary, to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. A brief description of the evaluation sheets is given below.

Components. See the description for the Compilations.

Evaluator. Name and date up to which the literature was checked.

Critical Evaluation

(a) Critical text. The evaluator produces text evaluating all the published data for each given system. Thus, in this section the evaluator review the merits or shortcomings of the various data. Only published data are considered; even published data can be considered only if the experimental data permit an assessment of reliability.

(b) Fitting equations. If the use of a smoothing equation is justifiable, the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets.

(c) Graphical summary. In addition to (b) above, graphical summaries are often given.

(d) Recommended values. Data are recommended if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are reported as tentative if only one set of measurements is available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as doubtful if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value in those instances where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are rejected. However references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) References. All pertinent references are given here. References to those data which, by virtue of their poor precision, have been rejected and not compiled are also listed in this section.

(f) Units. While the original data may be reported in the units used by the investigators, the final recommended values are reported in S.I. units (1,16) when the data can be accurately converted.

Two investigations of the solubility of LiCl in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm\(^{-3}\) and the conductance to below 2 \(\times 10^{-5}\) S m\(^{-1}\). The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 \(\times 10^{-5}\) S m\(^{-1}\). It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm\(^{-3}\). Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility. In neither investigation was the recommended method of drying the LiCl (by passing dry HCl) used, so that the purity of the solute is unknown.

Solubility at 298 K has been determined by Paul et al. (2) (250.6 g/kg of solvent) and by Berardelli et al. (3) (282 g/kg of solvent). Both groups of workers used purified solvent and took precautions to work in dry conditions. While the solvent used by Paul et al. (2) was probably the purer, no details are given of their analytical methods. The mean value of the two determinations is therefore recommended as a tentative value.

\[266 \pm 16\] g/kg of solvent

Tentative value at 298 K

Tentative value at 308 K and 318 K

Paul et al. (2) measured the solubility of LiCl in formamide at 308 K and 318 K. The results reported may be taken as tentative values:

\[211 \pm 11\] g/kg of solvent

308 K

\[185 \pm 10\] g/kg of solvent

318 K

### Auxiliary Information

#### Method/Apparatus/Procedure:

Saturated solutions of lithium chloride were prepared by adding excess of the powdered salt to formamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and heating to nearly 10 °C above the temperature of the bath. The attainment of the equilibrium was checked by intermittent analyses of the solutions. The solutions were then filtered under nitrogen and analysed for chloride. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

#### Source and Purity of Materials:

A.R. grade lithium chloride (BDH) was recrystallised, powdered and dried in vacuum at 110-125 °C.

Formamide (Reidel Pure) was distilled under reduced pressure after extensive prior purification (1). Purity was checked by conductance and density measurements. A conductance of 5 x 10$^{-5}$ S m was obtained. The solvent was stored in the dark.

#### Estimated Error:

- Solubility ± 1%
- Temperature ±0.05 °C (author)

CRITICAL EVALUATION:

Two investigations of the solubility of LiBr in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm⁻³. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

Solubility at 298 K has been determined by Paul et al. (2) (454.5 g/kg of solvent) and by Berardelli et al. (3) (738 g/kg of solvent). As both groups of workers used relatively pure solvent and dry conditions, there is no obvious explanation for this large discrepancy. The mean of these two determinations might be proposed as a very tentative value. Paul et al. (2) also measured the solubility at 308 K and 318 K:

### VARIABLES:

- One temperature: 25 °C

### EXPERIMENTAL VALUES:

**Solubility of lithium bromide in formamide at 25 °C**

73.8 g/100 g solvent.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water-free solutions and all the solutions were prepared in a dry box. Saturated lithium bromide solutions were prepared by dissolving excess of the halide in about 20-25 cm$^3$ of solvent contained in a 50 cm$^3$ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT 1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of formamide to aqueous solution (1:5). The equivalence point remained the same (1).

**SOURCE AND PURITY OF MATERIALS:**

Lithium bromide, reagent grade, was dried under high vacuum before use. Commercial formamide (C. Erba, RP Product) was purified by storing over CaO for 2 days before twice distilling under reduced pressure. The conductance of the formamide varied from 0.9 to 1.40 x 10$^{-4}$ S m$^{-1}$.

**ESTIMATED ERROR:**

- Solubility: ±1%
- Temperature: ±0.05 °C (author)

December 1978.

Critical Evaluation:

Four investigations of the solubility of NaCl in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm⁻³. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (3), a value of 99 g dm⁻³ of saturated solution at 298 K, cannot be compared with the molal solubilities given by the other workers since densities were not measured. However this result is likely to be high since the solvent was not purified and may have contained significant quantities of water.

Solubilities at 298 K determined by Paul et al. (2) (94.4 g/kg of solvent), Gopal and Husain (4) (93.2 g/kg of solvent) and by Berardelli et al. (5) (93.8 g/kg of solvent) are in good agreement. They have a mean value of 93.8 g/kg of solvent with a standard deviation of 0.8 g/kg of solvent, or just under 1%. There seems no good reason to favour one value over the others, and the mean value is therefore recommended.

Recommended value at 298 K

93.8 ± 0.8 g/kg of solvent

Values at other temperatures

Both Paul et al. (2) and Gopal et al. (4) report solubilities at higher temperatures. Agreement between the two sets of results is good. In order to utilise all the data, a regression analysis of all the values in (2), (4) and (5) was undertaken in which the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. A correlation coefficient of -0.980 was found and from the analysis the following values are recommended.

Recommended value at 308 K

89.1 ± 1.0 g/kg of solvent

Recommended value at 318 K

84.8 ± 1.0 g/kg of solvent

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of sodium chloride were prepared by adding excess of the powdered salt to formamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and heating to nearly 10 °C above the temperature of the bath. The attainment of the equilibrium was checked by intermittent analyses of the solutions. The solutions were then filtered under nitrogen and analysed for chloride. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade sodium chloride (BDH) was recrystallised, powdered and dried in vacuum at 110-125 °C. Formamide (Reidel Pure) was distilled under reduced pressure after extensive prior purification (1). Purity was checked by conductance and density measurements. A conductance of $5 \times 10^{-5} \, \text{S m}^{-1}$ was obtained. The solvent was stored in the dark.

ESTIMATED ERROR:

- Solubility ± 1%
- Temperature ± 0.05 °C (author)

(2) Formamide; CH₃NO; [75-12-7]

VARIABLES:
One Temperature: 25 °C

EXPERIMENTAL VALUES:

Solubility of sodium chloride in formamide at 25 °C.

9.38 g/100 g solvent.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated sodium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stored for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT 1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of formamide to aqueous solution (1:5). The equivalence point remained the same (1).

SOURCE AND PURITY OF MATERIALS:
Sodium chloride, reagent grade, was dried under high vacuum before use.
Commercial formamide (C. Erba, RP Product) was purified by storing over CaO for 2 days before twice distilling under reduced pressure. The conductance of the formamide varied from 0.9 to 1.40 x 10⁻⁴ S m⁻¹.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**
Saturated solutions of sodium chloride in formamide were prepared in glass containers so that an excess of solid was always present. After tumbling for a minimum of 48 hours in a thermostatted water bath the solutions were filtered quickly and aliquots taken for analysis.

The sodium was determined photometrically after decomposing the formamide. A Beckman DU spectrophotometric was used.

**SOURCE AND PURITY OF MATERIALS:**
Reagent grade sodium chloride.
Commercial formamide (Fisher Scientific Co.), with a freezing point of 2.50 °C was used without further purification.

**ESTIMATED ERROR:**
Solubility ± 5% (compiler)
Temperature ± 1 °C (author)

**REFERENCES:**

CRITICAL EVALUATION:  
Five investigations of the solubility of NaBr in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm⁻³. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (3) (a value of 439 g dm⁻³ of saturated solution at 298 K, which is equivalent to approximately 430 g/kg of solvent) is very much higher than that found by other workers. This result is rejected since no purification of the solvent was attempted.

Solubilities at 298 K determined by Paul et al. (2) (348.9 g/kg of solvent), Pavlopoulos and Strehlow (4) (304.7 g/kg of solvent), Gopal and Husain (5) (358.4 g/kg of solvent) and Berardelli et al. (6) (353 g/kg of solvent) have a mean value of 341.3 g/kg of solvent with a standard deviation of 25 g/kg of solvent, or just over 7%. By rejecting the value of Pavlopoulos and Strehlow on statistical grounds, a mean value of 353.4 ± 5.0 g/kg of solvent is found. This is consistent with the calculated value of 354.7 g/kg determined using a linear regression analysis of the logarithms of solubilities between 298 K and 323 K as a function of the reciprocal of the absolute temperature.

Recommended value at 298 K

353.4 ± 4.8 g/kg of solvent

Tentative values at other temperatures

Both Paul et al. (2) and Gopal and Husain (5) report solubilities at higher temperatures. Agreement between the two sets of values is fair. While the data of Paul et al. may be slightly more reliable at higher temperatures since their purer solvent would be less liable to decomposition, no information is available concerning their analytical procedures. In order to utilise all the variable temperature data available a regression analysis of all the values given in (2), (5) and (6) was undertaken in which the logarithm of the solubility was assumed to be a linear function of the inverse absolute temperature. A correlation coefficient of -0.982 was found. From this analysis the following tentative values at 308 K and 318 K are given.

308 K

387 ± 5 g/kg of solvent

318 K

421 ± 6 g/kg of solvent.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of NaBr were prepared at 10-15° above the temperature at which the solubility was to be measured before thermostating at the required temperature. Aliquots (3-5 cm$^3$) were withdrawn with a pro-pipette and weighed in a closed silica dish protected from moisture with P$_2$O$_5$. Two more samples were taken for each temperature and the amount of solute present determined by one of the following methods.

(1) Evaporation Method - Weighed samples were carefully heated to expel the solvent. The samples were then cooled and weighed in a dry atmosphere. The process was repeated to obtain a constant weight. All three samples taken were treated in a similar manner.

(2) Precipitation Method - Weighed samples of saturated solutions were diluted with water and the halide content was determined gravimetrically. Reliability of procedure was tested using known amounts of KCl in formamide and estimating gravimetrically. When experimental and theoretical values agreed within ±0.5% the procedure was applied to the samples of unknown solubility.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade sodium bromide.
Commercial formamide was redistilled and stored out of contact with light in amber-coloured bottles until used.

**ESTIMATED ERROR:**

Solubility $\pm$ 1%
Temperature $\pm$ 0.1 °C (compiler)

EXPERIMENTAL VALUES:

Solubility of sodium bromide in formamide at 25 °C

340 g/1000 cm³ of saturated solution.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Water free solutions (≤ 0.005%) were prepared in a special glass apparatus equipped with a magnetic stirrer which was placed in a thermostatted bath for several hours. The saturated solution was then forced out with dry air through a sinter, into a 50 cm³ measuring flask and weighed. The air was dried over CaCl₂. A known volume was evaporated to dryness, redissolved in water and the halogen content determined potentiometrically. No details of the cell were given (1). The results obtained were checked by density measurements.

SOURCE AND PURITY OF MATERIALS:
Reagent grade sodium bromide was dried at 240 °C for 4-5 hours in a furnace. Formamide (Merck) was dried over P₂O₅ and twice distilled, using a long column of glass helices, before use. The water content of the solvent was determined by Karl Fischer titration.

ESTIMATED ERROR:

Solubility ± 1%
Temperature ± 0.1 °C (author)

REFERENCES:

1. Pavlopoulos, T.; Strehlow, H.
Four investigations of the solubility of NaI in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm$^{-3}$ and the conductance to below $2 \times 10^{-5}$ S m$^{-1}$.

The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of $5 \times 10^{-5}$ S m$^{-1}$. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm$^{-3}$. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (3), a value of 752 g dm$^{-3}$ of saturated solution at 298 K, cannot be compared with the molal solubilities given by the other workers since densities were not measured. However this result is likely to be high since the solvent was not purified and may have contained significant quantities of water.

The solubilities determined by Paul et al. (2) and by Gopal and Husain (4) are in fair agreement over the temperature range studied. The greatest discrepancy occurs at 298 K, where solubilities of 656.3 g/kg of solvent and 566.2 g/kg of solvent respectively, are reported. Berardelli et al. (5) suggest the even more discrepant value of 850 g/kg of solvent. No simple explanation for this lack of agreement can be given. Analysis of the data suggested rejecting the result of Berardelli et al. (5). All the values from (2) and (4) were then subjected to a regression analysis where the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. Excellent linearity was found (correlation coefficient of -0.986), and from the analysis the following tentative values are suggested.

**Tentative value at 298 K**

$600 \pm 20$ g/kg of solvent

**Tentative value at 308 K**

$788 \pm 10$ g/kg of solvent

**Tentative value at 318 K**

$1038 \pm 15$ g/kg of solvent.

CRITICAL EVALUATION:

One investigation of the solubility of NaCNS in formamide has been reported (1). As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (2) is required to lower the water content to below 0.01 mol dm$^{-3}$ and the conductance to below $2 \times 10^{-5}$ S m$^{-1}$. In this study, careful solvent purification enabled a conductance of $5 \times 10^{-5}$ S m$^{-1}$ to be obtained. Unfortunately no detail is given of the analytical methods used to determine the solute concentration.

Measurements were made at 298, 308 and 318 K. As a check for internal consistency, the logarithms of the solubilities were plotted as a function of the reciprocal of the absolute temperature. An excellent linear relationship was obtained. While the results of only one investigation are available, it would appear that they have been determined with sufficient care for them to be taken as recommended values.

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of sodium thioazamate were prepared by adding excess of the powdered salt to formamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and heating to nearly 10⁰ above the temperature of the bath. The attainment of the equilibrium was checked by intermittent analyses of the solutions. The solutions were then filtered under nitrogen and analysed for chloride. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade sodium thiocyanate (BDH) was recrystallised, powdered and dried in vacuum at >100 °C.

Formamide (Reidel Pure) was finally distilled under reduced pressure after extensive prior purification (1). Purity was checked by conductance and density measurements. A conductance of 5 x 10⁻⁵ S m⁻¹ was obtained. The solvent was stored in the dark.

**ESTIMATED ERROR:**

Solubility ± 1%
Temperature ± 0.05 °C (author)

CRITICAL EVALUATION:

Five investigations of the solubility of KCl in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm⁻³. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (3) (a value of 80.8 g dm⁻³ of saturated solution at 298 K, which is equivalent to approximately 74.7 g/kg of solvent) is considerably higher than that found by other workers. This result is rejected since no purification of the solvent was attempted.

Solubilities at 298 K determined by Paul et al. (2) (62.9 g/kg of solvent), Pavlopoulos and Strehlow (4) (61.3 g/kg of solvent), Gopal and Husain (5) (63.0 g/kg of solvent) and Berardelli et al. (6) (61.8 g/kg of solvent) have a mean value of 62.3 g/kg of solvent with a standard deviation of 0.83 g/kg of solvent, or just over 1%. The results seem to fall into two groups with mean values of 61.5 ± 0.3 g/kg of solvent and 62.9 ± 0.1 g/kg of solvent, but it is not possible to select one of these as the better estimate. While the solvent used by Paul et al. (2) was particularly pure, no details are given of their analytical methods. The solvent used by Gopal and Husain (5) was unlikely to have been very dry. Both Pavlopoulos and Strehlow (4) and Berardelli et al. (6) took special precautions to prepare pure solvent and to work in a dry atmosphere. The latter groups used potentiometric titration to determine the chloride ion in solution.

Recommended value at 298 K

62.3 ± 0.8 g/kg of solvent

Tentative values at other temperatures

Both Paul et al. (2) and Gopal and Hussain (5) report solubilities at higher temperatures. Agreement between the two sets of data is very good at 298 K, but the values diverge as the temperature is raised until by 318 K the difference is over 3%. While the data of Paul et al. may be slightly more reliable at higher temperatures since their purer solvent would be less liable to decomposition, mean values are reported below as tentative best values. No significant difference is found between these and values determined using a linear regression analysis of the logarithm of all the solubilities as a function of the reciprocal of the absolute temperature. The only measurement reported at temperatures lower than 298 K is one at 291 K by Pavlopoulos and Strehlow (4). Their value of 60.3 g/kg of solvent compares with 61.2 g/kg of solvent obtained by extrapolation of the best straight line through all the other points, and thus may be somewhat low. The error in the solubilities at temperatures other than 298 K is estimated to be ±1.5%.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**
Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated potassium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stored for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gouch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT 1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of formamide to aqueous solution (1:5). The equivalence point remained the same (1).

**SOURCE AND PURITY OF MATERIALS:**
Potassium chloride, reagent grade, was dried under high vacuum before use. Commercial formamide (C. Erba, RP product) was purified by storing over CaO for 2 days before twice distilling under reduced pressure. The conductance of the formamide varied from 0.9 to 1.40 x 10⁻⁴ S m⁻¹.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**
Saturated solutions of KCl were prepared at 10-15 °C above the temperature at which the solubility was to be measured before thermostating at the required temperature. Aliquots (3-5 cm³) were withdrawn with a pro-pipette and weighed in a closed silica dish protected from moisture with P₂O₅. Two more samples were taken for each temperature and the amount of solute present determined by one of the following methods.

1. **Evaporation Method** - Weighed samples were carefully heated to expel the solvent. The samples were then cooled and weighed in a dry atmosphere. The process was repeated to obtain a constant weight. All three samples taken were treated in a similar manner.

2. **Precipitation Method** - Weighed samples of saturated solutions were diluted with water and the halide content was determined gravimetrically. Reliability of procedure was tested using known amounts of KCl in formamide and estimating gravimetrically. When experimental and theoretical values agreed within ±0.5% the procedure was applied to the samples of unknown solubility.

**SOURCE AND PURITY OF MATERIALS:**
A.R. grade potassium chloride. Commercial formamide was redistilled and stored out of contact with light in amber-coloured bottles until used.

**ESTIMATED ERROR:**
- Solubility ± 1%
- Temperature ± 0.1 °C (compiler)

### Auxilliary Information

#### Method/Apparatus/Procedure:

Water free solutions (≤ 0.005%) were prepared in a special glass apparatus equipped with a magnetic stirrer which was placed in a thermostatted bath for several hours. The saturated solution was then forced out with dry air through a sinter, into a 50 cm³ measuring flask and weighed. The air was dried over CaCl₂. A known volume was evaporated to dryness, redissolved in water and the halogen content determined potentiometrically. No details of the cell were given (1). The results obtained were checked by density measurements.

#### Source and Purity of Materials:

Reagent grade potassium chloride was dried at 240 °C for 4-5 hours in a furnace. Formamide (Merck) was dried over P₂O₅ and twice distilled, using a long column of glass helices before use.

The water content of the solvent was determined by Karl Fischer titration.

#### Estimated Error:

- Solubility ± 1%
- Temperature ± 0.1 °C (author)

#### References:

December 1978.

CRITICAL EVALUATION:
Three investigations of the solubility of KBr in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm\(^{-3}\) and the conductance to below 2 \(\times 10^{-5}\) S m\(^{-1}\). The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 \(\times 10^{-5}\) S m\(^{-1}\). It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm\(^{-3}\). Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

Solubilities at 298 K determined by Paul et al. (2) (216.1 g/kg of solvent), Gopal and Husain (3) (213.8 g/kg of solvent) and by Berardelli et al. (4) (216 g/kg of solvent) are in excellent agreement. They have a mean value of 215.3 g/kg of solvent with a standard deviation of 1.3 g/kg of solvent, or 0.6%. There seems no good reason to favour one value over the others, and the mean value is therefore recommended.

Recommended value at 298 K

\[ 215.3 \pm 1.3 \text{ g/kg of solvent} \]

Values at other temperatures

Both Paul et al. (2) and Gopal and Husain (3) report solubilities at higher temperatures. The temperature coefficient was found to be small. Agreement between the two sets of results is excellent. In a regression analysis of all the results where the logarithm of the solubility was assumed to be a linear function of the inverse absolute temperature, a correlation coefficient of \(-0.961\) was found. The mean values of the two determinations at 308 K and 318 K are therefore recommended.

Recommended value at 308 K

\[ 217.8 \pm 1.3 \text{ g/kg of solvent} \]

Recommended value at 318 K

\[ 221.4 \pm 1.3 \text{ g/kg of solvent} \]

**CRITICAL EVALUATION:**

Five investigations of the solubility of KI in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹. It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm⁻³. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

Solubilities at 298 K determined by Paul et al. (2) (685.0 g/kg of solvent), Colton and Brooker (3) (692 g/kg of solvent – evaluator, using density data from (4)), Pavlopoulos and Strehlow (4) (669.4 g/kg of solvent), Gopal and Husain (5) (692.2 g/kg of solvent) and by Berardelli et al. (6) (678 g/kg of solvent) have a mean value of 683 g/kg of solvent with a standard deviation of 10 g/kg of solvent. It is difficult to select the best determination. The two highest values occur with solvents where least care has been taken to eliminate water and these results are probably greater than the true value. On the other hand, values given by Pavlopoulos and Strehlow (4) for KCl and KI in formamide have been lower than those reported by other workers using dry solvents. It has therefore been decided to recommend the mean value.

**Recommend value at 298 K**

683 ± 10 g/kg of solvent

**Tentative values at other temperatures**

Both Paul et al. (2) and Gopal and Husain (5) report solubilities at higher temperatures. The temperature coefficient for the solubility of KI in formamide is very small and the two sets of results are in good agreement. However, in consideration of the significantly lower solubilities reported at 298 K by other workers only tentative values are suggested. In order to give some weighting to the results of Berardelli et al. (6) and Pavlopoulos and Strehlow (4) a regression analysis of all the values was undertaken in which the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. From this analysis the following tentative values at 308 K and 318 K are given.

308 K

691 ± 10 g/kg of solvent

318 K

698 ± 10 g/kg of solvent.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of potassium iodide were prepared by adding excess of the powdered salt to formamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and heating to nearly 10 °C above the temperature of the bath. The attainment of the equilibrium was checked by intermittent analyses of the solutions. The solutions were then filtered under nitrogen and analysed for iodide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade potassium iodide (BDH) was recrystallised, powdered and dried in vacuum at 110-125 °C.
Formamide (Reidel Pure) was distilled under reduced pressure after extensive prior purification (1). Purity was checked by conductance and density measurements. A conductance of 5 x 10$^{-5}$ S m$^{-1}$ was obtained. The solvent was stored in the dark.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

Solubility of potassium iodide in formamide at 25 °C

67.8 g/100 g solvent.

**PREPARED BY:**

J.S. McKechnie

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water-free solutions and all the solutions were prepared in a dry box. Saturated potassium iodide solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stored for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of the dissolved halide determined by a potentiometric method using a titrimerator (type Radiometer TTT 1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of formamide to aqueous solution (1:5). The equivalence point remained the same (1).

**SOURCE AND PURITY OF MATERIALS:**

Potassium iodide, reagent grade, was dried under high vacuum before use. Commercial formamide (C. Erba, RP Product) was purified by storing over CaO for 2 days before twice distilling under reduced pressure. The conductance of the formamide varied from 0.9 to 1.40 x 10⁻⁴ S m⁻¹.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of KI were prepared at 10-15 ° above the temperature at which the solubility was to be measured before thermostating at the required temperature. Aliquots (3-5 cm³) were withdrawn with a pro-pipette and weighed in a closed silica dish protected from moisture with P₂O₅. Two more samples were taken for each temperature and the amount of solute present determined by one of the following methods.

1. **Evaporation Method** - Weighed samples were carefully heated to expel the solvent. The samples were then cooled and weighed in a dry atmosphere. The process was repeated to obtain a constant weight. All three samples taken were treated in a similar manner.

2. **Precipitation Method** - Weighed samples of saturated solutions were diluted with water and the halide content was determined gravimetrically. Reliability of procedure was tested using known amounts of KCl in formamide and estimating gravimetrically. When experimental and theoretical values agreed within ±0.5% the procedure was applied to the samples of unknown solubility.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade potassium iodide.
Commercial formamide was redistilled and stored out of contact with light in amber-coloured bottles until used.

EXPERIMENTAL VALUES:

Solubility of potassium iodide in formamide at 25 °C

616 g/1000 cm³ of saturated solution.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Water free solutions (< 0.005%) were prepared in a special glass apparatus equipped with a magnetic stirrer which was placed in a thermostatted bath for several hours. The saturated solution was then forced out with dry air through a sinter, into a 50 cm³ measuring flask and weighed. The air was dried over CaCl₂. A known volume was evaporated to dryness, redissolved in water and the halogen content determined potentiometrically. No details of the cell were given (1). The results obtained were checked by density measurements.

SOURCE AND PURITY OF MATERIALS:

Reagent grade potassium iodide was dried at 240 °C for 4-5 hours in a furnace. Formamide (Merck) was dried over P₂O₅ and twice distilled, using a long column of glass helices, before use. The water content of the solvent was determined by Karl Fischer titration.

ESTIMATED ERROR:

- Solubility ± 1%
- Temperature ± 0.1 °C (author)

REFERENCES:

CRITICAL EVALUATION:

One investigation of the solubility of KCN in formamide has been reported (1). As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid and a very elaborate purification procedure (2) is required to lower the water content to below 0.01 mol dm\(^{-3}\) and the conductance to below 2 \times 10^{-5}\) S m\(^{-1}\). In this investigation of KCN, no attempt was made to dry or purify the solvent. Since preferential solvation of the ions by water is probable, the value given probably represents the higher limit of solubility.

Tentative value at 298 K

\[ 146 \pm 8 \text{ g dm}^{-3} \text{ of saturated solution} \]

December 1978

CRITICAL EVALUATION:
Three investigations of the solubility of KCNS in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm\(^{-3}\) and the conductance to below 2 \(\times 10^{-5}\) S m\(^{-1}\).
The most stringent procedure used so far in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 \(\times 10^{-5}\) S m\(^{-1}\). It is likely that most of the solutions studied had water contents in the range 0.05 to 0.5 mol dm\(^{-3}\). Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (3), a value of 659 g dm\(^{-3}\) of saturated solution at 298 K, cannot be compared with the molal solubilities given by the other workers since densities were not measured. The solubilities at 298 K determined by Paul et al. (2) (1435.0 g/kg of solvent) and by Becker (4) (886 g/kg of solvent) are so far apart that it is difficult to recommend even a tentative value for this solute. Measurements at 308 and 318 K by Paul et al. (2) indicate that the temperature coefficient of solubility is very small. However the rate of dissolution may be significantly affected by temperature. Paul et al. heat their samples initially at 10 °C above the temperature of the bath before cooling to the equilibration temperature. Becker (4) maintained his solutions at 25 °C throughout the 48 hour equilibration period and it is therefore possible that his solutions did not saturate because of slow dissolution kinetics.

Tentative values 298 to 318 K

1420 ± 20 g/kg of solvent.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions were prepared by shaking excess potassium thiocyanate with the solvent for at least 48 hours in a thermostatted bath. The formamide was exposed to air only briefly during addition. The mixture was filtered rapidly in air at 25 °C and a weighed aliquot of the filtrate was taken for analysis. Two or three separate solubility determinations were made for each compound. Before analysis, formamide was removed by evaporating an aqueous solution of the sample to dryness. Potassium was determined by the Perrin method (1), which involved weighing the potassium precipitated as K₂PtCl₆.

**SOURCE AND PURITY OF MATERIALS:**

Reagent grade potassium thiocyanate. Formamide (Matheson, Coleman and Bell, 99%) was used without further purification. Its melting point of 2.5 °C ± 0.1 °C was in good agreement with the literature value of 2.55 °C.

VARIABLES:

One temperature: 25°C

EXPERIMENTAL VALUES:

Solubility of caesium chloride in formamide at 25°C

91.5 g/1000 cm³ of saturated solution

Value calculated from solubility product data given as:

\[ \log(K_s/mol \ dm^{-3}) = -0.53 \]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Saturated solutions of caesium chloride were prepared by shaking the solid with solvent in a stoppered flask at 35°C for 24 hours. The flask was then shaken for a further 24 hours at 25°C. The liquid phase was analysed for halide potentiometrically using silver concentration cells with a tetraethylammonium picrate salt bridge. The cells were wrapped in aluminium foil and immersed in a 25°C thermostat and stirred magnetically, as standard 0.01 mol dm⁻³ silver nitrate was added. The emf was measured on a Radiometer pH meter (type PHM 22r). It was established early in the work that effectively the same results were obtained no matter whether measurements were made in the dark or freshly prepared solutions, or on solutions exposed to the atmosphere for 30 minutes, or on solutions kept under dry nitrogen during preparation and titration. The usual procedure was to titrate 0.01 mol dm⁻³ AgNO₃ solution into a half-cell containing the silver wire immersed in 20 cm³ of 0.01 mol dm⁻³ caesium chloride in formamide. The reference half-cell was a silver wire in 0.01 mol dm⁻³ AgNO₃ in the same solvent.

SOURCE AND PURITY OF MATERIALS:

A.R. grade caesium chloride was used without further purification. Formamide was dried with Type 4A molecular sieves and fractionated twice under a reduced pressure of dry nitrogen. It was stored over molecular sieves in dark bottles and was used within 7 days of purification. The silver nitrate solution turned brown, slowly, but the concentration of silver ion when estimated by titration with potassium bromide, was as required by the stoichiometric amount of silver nitrate.

ESTIMATED ERROR:

Solubility ± 2% (compiler)
Temperature ± 0.1°C (compiler)

### Experimental Values:

Solubility of caesium iodide in formamide at 25 °C

199.4 g/1000 cm³ of saturated solution.

Value calculated from solubility product data given as:

\[
\log (K_o/\text{mol dm}^{-3}) = -0.23
\]

### Auxiliary Information

**Method/Apparatus/Procedure:**

Saturated solutions of caesium iodide were prepared by shaking the solid with solvent in a stoppered flask at 35 °C for 24 hours. The flask was then shaken for a further 24 hours at 25 °C. The liquid phase was analysed for halide potentiometrically using silver concentration cells with a tetrachloroalumimum picrate salt bridge. The cells were wrapped in aluminium foil and immersed in a 25 °C thermostat and stirred magnetically, as standard 0.01 mol dm⁻³ silver nitrate was added. The emf was measured on a Radiometer pH meter (type PHM 22r). It was established early in the work that effectively the same results were obtained no matter whether measurements were made in the dark on freshly prepared solutions, on solutions exposed to the atmosphere for 30 minutes, or on solutions kept under dry nitrogen during preparation and titration. The usual procedure was to titrate 0.01 mol dm⁻³ AgNO₃ solution into a half-cell containing the silver wire immersed in 20 cm³ of 0.01 mol dm⁻³ caesium iodide in formamide. The reference half-cell was a silver wire in 0.01 mol dm⁻³ AgNO₃ in the same solvent.

**Source and Purity of Materials:**

A.R. grade caesium iodide was used without further purification.

Formamide was dried with Type 4A molecular sieves and fractionated twice under a reduced pressure of dry nitrogen. It was stored over molecular sieves in dark bottles and was used within 7 days of purification. The silver nitrate solution turned brown, slowly, but the concentration of silver ion when estimated by titration with potassium bromide, was as required by the stoichiometric amount of silver nitrate.

**Estimated Error:**

Solubility ± 2% (compiler)

Temperature ± 1 °C (compiler)

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**

Water free solutions (≤ 0.005%) were prepared in a special glass apparatus equipped with a magnetic stirrer which was placed in a thermostatted bath for several hours. The saturated solution was then forced out with dry air through a sinter, into a 50 cm³ measuring flask and weighed. The air was dried over CaCl₂. A known volume was evaporated to dryness, redissolved in water and the halogen content determined potentiometrically. No details of the cell were given (1). The results obtained were checked by density measurements.

**SOURCE AND PURITY OF MATERIALS:**

Reagent grade caesium iodide was dried at 240 °C for 4-5 hours in a furnace. Formamide (Merck) was dried over P₂O₅ and twice distilled, using a long column of glass helices, before use. The water content of the solvent was determined by Karl Fischer titration.

**ESTIMATED ERROR:**

| Solubility | ± 1% |
| Temperature | ± 0.1 °C (author) |

**REFERENCES:**

Two sets of values have been reported for the solubility of NH₄Cl in formamide. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. The most stringent procedure used in solubility studies has been that of Paul et al. (2) who obtained a conductance of 5 x 10⁻⁵ S m⁻¹.

Measurements on the solubility of NH₄Cl were made at three temperatures by Paul et al. (2) and at six temperatures by Gopal and Husain (3). Evaluations at common temperatures agree to better than 0.6%. In a regression analysis of all nine results where the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature, a correlation coefficient of -0.994 was found. On the basis of this analysis the following solubility values are recommended.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of ammonium chloride were prepared by adding excess of the powdered salt to formamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and heating to nearly 10 °C above the temperature of the bath. The attainment of the equilibrium was checked by intermittent analyses of the solutions. The solutions were then filtered under nitrogen and analysed for chloride. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade ammonium chloride (BDH) was recrystallised, powdered and dried in vacuum at 110-125 °C.

Formamide (Reidel Pure) was distilled under reduced pressure after extensive prior purification (1). Purity was checked by conductance and density measurements. A conductance of $5 \times 10^{-5} \text{ S m}^{-1}$ was obtained. The solvent was stored in the dark.

**ESTIMATED ERROR:**

Solubility $±$ 1%
Temperature $±$ 0.05 °C (author)

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of \( \text{NH}_4\text{Cl} \) were prepared at 10-15° above the temperature at which the solubility was to be measured before thermostating at the required temperature. Aliquots (3-5 cm³) were withdrawn with a pro-pipette and weighed in a closed silica dish protected from moisture with \( \text{P}_2\text{O}_5 \).

Two more samples were taken for each temperature and the amount of solute present determined by one of the following methods.

1. **Evaporation Method** - Weighed samples were carefully heated to expel the solvent. The samples were then cooled and weighed in a dry atmosphere. The process was repeated to obtain a constant weight. All three samples taken were treated in a similar manner.

2. **Precipitation Method** - Weighed samples of saturated solutions were diluted with water and the halide content was determined gravimetrically. Reliability of procedure was tested using known amounts of KCl in formamide and estimating gravimetrically. When experimental and theoretical values agreed within ±0.5% the procedure was applied to the samples of unknown solubility.

### SOURCE AND PURITY OF MATERIALS:

A.R. grade ammonium chloride.

Commercial formamide was redistilled and stored out of contact with light in amber-coloured bottles until used.

CRITICAL EVALUATION:
One investigation of the solubility of NH$_4$CNS in formamide has been reported (1).
As in other measurements of salt solubility in this solvent, the accuracy of the
data is likely to be determined primarily by the purity of the solvent used, rather
than by the precision of the analytical methods. Formamide is a thermally unstable,
photosensitive and hygroscopic liquid, and a very elaborate purification procedure (2)
is required to lower the water content to below 0.01 mol dm$^{-3}$ and the conductance to
below 2 x 10$^{-5}$ S m$^{-1}$. In this study, careful solvent purification enabled a
conductance of 5 x 10$^{-5}$ S m$^{-1}$ to be obtained. Unfortunately no detail is given
of the analytical methods used to determine the solute concentration.

Measurements were made at 298, 308, and 318 K. As a check for internal
consistency, the logarithms of the solubilities were plotted as a function of the
reciprocal of the absolute temperature. An excellent linear relationship was
obtained. While the results of only one investigation are available, it would
appear that they have been determined with sufficient care for them to be taken
as recommended values.

Recommended values
298 K
1015.5 $\pm$ 6.0 g/kg of solvent
308 K
1102.0 $\pm$ 6.0 g/kg of solvent
318 K

December 1978.

CRITICAL EVALUATION:
One investigation of the solubility of MgCl₂ in formamide has been reported (1).
As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (2) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. In this study, the conductance of the formamide was in the range 0.9 to 1.4 x 10⁻⁴ S m⁻¹.

While the result of only this one investigation is available, it would appear that the measurement has been undertaken with sufficient care for it to be taken as a recommended value. Good agreement has been shown between the results for CaCl₂ obtained by the above workers and those of Gopal and Husain (3). However the recommended method of preparing anhydrous MgCl₂ (by passing dry HCl over the hydrated double salt, MgCl₂ • NH₄Cl) was not followed and so the purity of the solute is unknown. Hence only a tentative value for the solubility is recommended.

Tentative value at 298 K
84 ± 4 g/kg of solvent.

December 1978

CRITICAL EVALUATION:

Three investigations of the solubility of CaCl₂ in formamide have been reported. As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (1) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. Since preferential solvation of the ions by water is probable, use of wet solvent might give rise to elevated estimates of solubility.

The solubility reported by Colton and Brooker (2), a value of 222 g/dm⁻³ of saturated solution at 298 K, cannot be compared with the molal solubilities given by the other workers since densities were not measured. However this result is likely to be high since the solvent was not purified and may have contained significant quantities of water.

The solubility at 298 K was measured by Berardelli et al. (3) and at five temperatures between 308 and 328 K by Gopal and Husain (4). To check the consistency of the two investigations, all six values were subjected to a regression analysis where the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. Excellent linearity was found (correlation coefficient -0.993).

</tr>
</tbody>
</table>

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated calcium chloride solutions were prepared by dissolving excess of the halide in about 3 20-25 cm$^3$ of solvent contained in a 50 cm$^3$ Pyrex flask with a standard taper joint. The solution was then stored for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT 1) and, presumably, standard aqueous silver nitrate. Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of formamide to aqueous solution (1:5). The equivalence point remained the same (1).

**AUXILIARY INFORMATION**

**SOURCE AND PURITY OF MATERIALS:**

Calcium chloride, reagent grade, was dried under high vacuum before use. Commercial formamide (C. Erba, RP Product) was purified by storing over CaO for 2 days before twice distilling under reduced pressure. The conductance of the formamide varied from 0.9 to 1.40 x 10$^{-4}$ S m$^{-1}$.

**ESTIMATED ERROR:**

Solubility ± 1%
Temperature ± 0.05 °C (author)

### AUXILIARY INFORMATION

#### METHOD/APPARATUS/PROCEDURE:

Saturated solutions of CaCl₂ were prepared at 10-15°C above the temperature at which the solubility was to be measured before thermostating at the required temperature. Aliquots (3-5 cm³) were withdrawn with a pro-pipette and weighed in a closed silica dish protected from moisture with P₂O₅. Two more samples were taken for each temperature and the amount of solute present determined by one of the following methods.

1. Evaporation Method - Weighed samples were carefully heated to expel the solvent. The samples were then cooled and weighed in a dry atmosphere. The process was repeated to obtain a constant weight. All three samples taken were treated in a similar manner.

2. Precipitation Method - Weighed samples of saturated solutions were diluted with water and the halide content was determined gravimetrically. Reliability of procedure was tested using known amounts of KCl in formamide and estimating gravimetrically. When experimental and theoretical values agreed within ±0.5% the procedure was applied to the samples of unknown solubility.

### SOURCE AND PURITY OF MATERIALS:

A.R. grade calcium chloride.

Commercial formamide was redistilled and stored out of contact with light in amber-coloured bottles until used.

### ESTIMATED ERROR:

| Solubility | ± 1% |

**EXPERIMENTAL VALUES:**

Solubility of calcium chloride in formamide at 25 °C

222 g/1000 cm$^3$ of saturated solution

---

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of calcium chloride in formamide were prepared in glass containers so that an excess of solid was always present. After tumbling for a minimum of 48 hours in a thermostatted water bath the solutions were filtered quickly and aliquots taken for analysis. Duplicate samples were run.

The calcium was determined photometrically after decomposing the formamide. A Beckman DU spectrophotometer was used.

---

**SOURCE AND PURITY OF MATERIALS:**

Reagent grade calcium chloride.  
Commercial formamide (Fisher Scientific Co) with a freezing point of 2.50 °C was used without further purification.

---

**ESTIMATED ERROR:**

Solubility $\pm$ 5% (compiler)  
Temperature $\pm$ 1 °C (author)

---

CRITICAL EVALUATION:

One investigation of the solubility of CaBr₂ in formamide has been reported (1). As in other measurements of salt solubility in this solvent, the accuracy of the data is likely to be determined primarily by the purity of the solvent used, rather than by the precision of the analytical methods. Formamide is a thermally unstable, photosensitive and hygroscopic liquid, and a very elaborate purification procedure (2) is required to lower the water content to below 0.01 mol dm⁻³ and the conductance to below 2 x 10⁻⁵ S m⁻¹. In this study, the conductance of the formamide was in the range 0.9 to 1.4 x 10⁻⁴ S m⁻¹.

While the result of only this one investigation is available, it would appear that the measurement has been undertaken with sufficient care for it to be taken as a recommended value. Good agreement has been shown between the results for CaCl₂ obtained by the above workers and those of Gopal and Husain (3).

Recommended value at 298 K

434 ± 4 g/kg of solvent.

December 1978.

CRITICAL EVALUATION:
Three investigations of the solubility of LiCl in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls, and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was 5 x 10⁻⁵ S m⁻¹, which is as low as that reported in any investigation of this solvent.

A major problem in the determination of the solubility of LiCl in N-methylformamide has, however, been detected by Strack et al. (1). These workers have shown that the equilibrium state of the solid phase is almost certainly a solvate, although its composition was not determined. Further, not only was the normal solubility equilibrium impossible to measure with any certainty, but no equilibrium of any kind had been established at the end of three weeks at 298 K.

An additional problem is that none of the investigators followed the recommended procedure for preparing anhydrous LiCl (by passing dry HCl over the salt) so that the purity of the solute is unknown.

A mean value for the solubility of LiCl of 230 ± 20 g/kg of solvent is obtained if results from all three investigations are considered. However in view of the likelihood of solvate formation, no recommended value is given for this salt.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**
Saturated solutions of lithium chloride were prepared by adding excess of the powdered salt to N-methylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**
A.R. grade lithium chloride (BDH) was crystallised and dried under vacuum at 110-125 °C.
N-methylformamide was purified by fractionation of the solvent over sodamide in a dry nitrogen atmosphere and had the following physical constants: B.Pt. 52-53 °C/1 mm; specific conductance 3-4 x 10^{-5} S m^{-1}; density 0.9986 g/cm^3; refractive index 1.4312 at 25 °C. The solvent was stored in dark coloured bottles and kept in a dry box. Physical constants were rechecked before use.

**ESTIMATED ERROR:**
Solubility ± 1%

**ORIGINAL MEASUREMENTS:**

**VARIABLES:**

One temperature: 25 °C

**EXPERIMENTAL VALUES:**

Solubility of lithium chloride in N-methylformamide at 25 °C

23.9 g/100 g solvent

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated lithium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm\textsuperscript{3} of solvent contained in a 50 cm\textsuperscript{3} Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT1) and, presumably, standard aqueous silver nitrate. Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of N-methylformamide to aqueous solution (1:5). The equivalence point remained the same(1).

**SOURCE AND PURITY OF MATERIALS:**

Lithium chloride, reagent grade, was dried under high vacuum before use. N-methylformamide (Fluka product) was purified by storing over CaO for two days before twice distilling under reduced pressure. The conductance of the N-methylformamide varied from 3.0 to 6.0 x 10\textsuperscript{-4} S m\textsuperscript{-1}.

Critical Evaluation:

Two investigations of the solubility of LiBr in N-methylformamide have been reported (1-2). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (3). Later Feakins and Lawrence (4) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use.

In the second of the current solubility studies (that by Paul et al. (2)), the solvent conductance was 5 x 10⁻⁵ S m⁻¹, which is as low as that reported in any investigation of this solvent. The solvent used by Berardelli et al. (1) had a mean conductance of 5 x 10⁻⁴ S m⁻¹.

In a parallel study of the solubility of LiCl in N-methylformamide, Strack et al. (5) showed that the equilibrium state of the solid phase was not pure LiCl, but a solvate of unidentified composition. The formation of such a phase made the determination of the solubility of LiCl virtually impossible. While no reference to solvate formation by LiBr in N-methylformamide is made by either group, the disparate results obtained (540 g/kg of solvent (1) and 352 g/kg of solvent (2) at 298 K) suggest that such a phenomenon may also occur with this salt. It might be noted that equilibrium had still not been established with LiCl after three weeks. No recommended value is therefore given for LiBr.

CRITICAL EVALUATION:
Three investigations of the solubility of NaCl in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls, and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was 5 \times 10^{-5} S m^{-1}, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of NaCl.

The solubilities reported at 298 K by Strack et al. (1) (32.2 g/kg of solvent) and by Berardelli et al. (2) (32.9 g/kg of solvent) are in excellent agreement. The value given by Paul et al. (3) (56.0 g/kg of solvent) is almost a factor of two higher and is rejected. There is no obvious reason for such a discrepancy, but it might be noted that solubilities quoted by Paul et al. for chlorides in N-methylformamide are generally higher than those given by other groups. No details of analytical methods were given by Paul et al. (3).

Recommended value at 298 K
32.6 \pm 1.0 g/kg of solvent.

Tentative values at other temperatures
Strack et al. (1), who measured solubilities over the temperature range 273-308 K, do not quote values at temperatures other than 298 K, but report a linear relationship between molal solubility and temperature, with a slowly increasing solubility with decreasing temperature. Paul et al. (3) who give values at 308 K and 318 K show a very sharp rise in solubility with decreasing temperature. Consideration of these results leads to, at best, an estimate of a minimum value of the solubility of 30.6 g/kg of solvent at 308 K.

**METHOD/APPARATUS/PROCEDURE:** (continuation)

As the densities were used to calculate concentrations on the molar scale the results are estimated to be accurate to within 2% on that scale, and to within 1% on the molal and mole ratio scales.

The solubilities in molal units were found to be linear functions of temperature over the range 0-35 °C. The constants A and B in the equation m = AT + B were determined for each salt by linear regression analysis. No information is given concerning the standard errors of the regression coefficients. However by comparing the solubilities quoted for direct measurements at 25 °C with those derived from the linear equations, the calculated solubilities are within 0.6 - 2.5% of those derived by direct measurements.

**SOURCE AND PURITY OF MATERIALS:** (continuation)

10⁻¹ and 10⁻² S m⁻¹. It was stored in tightly-stoppered brown glass bottles at room temperature.

The physical constants of the N-methylformamide were (literature values in parentheses):

\[
\begin{align*}
n_D^{25} & = 1.4305 \quad [1.4300 (4), 1.4310 (2)]; \\
\rho_4 & = 1.01 \quad [1.008 \text{ at } 15 \degree C (5)]; \\
\text{B.pt.} & = 62 \degree C \text{ at } 6 \text{ mm. of Hg} \quad [51 \degree C \text{ at } 1 \text{ mm of Hg} (5)].
\end{align*}
\]

In all cases, salts and solvent were stored and transferred in such a manner as to minimise the absorption of atmospheric moisture, presumably by the use of a dry box.

CRITICAL EVALUATION:

Three investigations of the solubility of NaBr in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls, and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was 5 x 10⁻⁵ S m⁻¹, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of NaBr.

The solubilities reported at 298 K by all three groups show good agreement, having a mean value of 298.1 g/kg of solvent and a standard deviation of 9.8 g/kg of solvent, or 3%. There are no compelling grounds for rejecting the highest value (that of Berardelli et al. (2)) although the solvent used had a higher conductance than in the other studies. The mean of the three investigations is therefore taken to be the recommended value.

**Recommended value at 298 K**

298 ± 10 g/kg of solvent

Tentative values at other temperatures.

Strack et al. (1), who measured solubilities over the temperature range 273-308 K, do not quote values at temperatures other than 298 K, but report a linear relationship between molal solubility and temperature. Paul et al. (3) give values at 308 K and 318 K. At 308 K, the calculated value from (1), namely 283 g/kg of solvent is in reasonable agreement with that given in (3), 289.9 g/kg of solvent. Thus despite the fact that Paul et al. gave no details of their analytical methods, the following tentative values are probably acceptable:

308 K

287 ± 10 g/kg of solvent

318 K

277 ± 10 g/kg of solvent.

**EXPERIMENTAL VALUES:**

Solubility of sodium bromide in N-methylformamide at 25 °C

28.6 g/100 g solvent

Within the temperature range 0-35 °C the solubilities in g/100 g of solvent, S, are given by:

\[ S = -0.124 T + 66.59 \]

Where T is the absolute temperature.

---

**METHOD/APPARATUS/PROCEDURE:**

An excess of sodium bromide and 10 cm\(^3\) of N-methylformamide in a carefully stoppered test tube were placed in a constant temperature bath for 2-4 days. The test tubes were shaken several times each day. Saturation was assumed when samples taken at least one day apart gave identical concentrations. 5 cm\(^3\) samples were withdrawn with a pipette equipped with a glass wool filter over the tip, and transferred to a glass stoppered weighing bottle. The contents of the weighing bottle were diluted to 100 cm\(^3\) with water and the halide titrated by Fajan's method. To check the reliability of the method, known samples of halide salts mixed with N-methylformamide in water were analysed and the results reported as excellent. Berger and Dawson (1) also report successful analyses of halides in the presence of formamide by Fajan's method. Densities were not as accurate as the corresponding weight data since they relied on temperature dependent pipette volumes. As the densities were used to calculate concentrations on the molar scale the

**SOURCE AND PURITY OF MATERIALS:**

Anhydrous A.R. grade sodium bromide was used without further purification after drying at 105 °C for 24 hours.

N-methylformamide was prepared by either of two methods: the addition of methylamine to formic acid (2) or by the classical method of the addition of methylamine to ethyl formate (3). The N-methylformamide was fractionally recrystallised until the conductance reached a value of between 10\(^{-1}\) and 10\(^{-2}\) S m\(^{-1}\). It was stored in tightly

**ESTIMATED ERROR:**

Solubility ± 1%

Temperature ± 0.1 °C (author)

**REFERENCES:**

### Method/Apparatus/Procedure:

Results are estimated to be accurate to within 2% on that scale, and to within 1% on the molal and mole ratio scales.

The solubilities in molal units were found to be linear functions of temperature over the range 0-35 °C. The constants A and B in the equation \( m = AT + B \) were determined for each salt by linear regression analysis. No information is given concerning the standard errors of the regression coefficients. However, by comparing the solubilities quoted for direct measurements at 25 °C with those derived from the linear equations, the calculated solubilities are within 0.6 - 2.5% of those derived by direct measurement.

### Source and Purity of Materials:

Stopped brown glass bottles at room temperature.

The physical constants of the N-methylformamide were (literature values in parentheses):

- \( n_D^{25} = 1.4305 \ [1.4300(4), 1.4310(2)] \)
- \( d_4^{21} = 1.01 \ [1.008 \text{ at } 15^\circ \text{C}(5)] \)
- B.P. = 62 °C at 6 mm of Hg [51 °C at 1 mm of Hg(5)].

In all cases, salts and solvent were stored and transferred in such a manner as to minimise the absorption of atmospheric moisture, presumably by the use of a dry box.

EVALUATOR:

C.A. Vincent, 
Department of Chemistry, 
University of St. Andrews, 
St. Andrews, Fife, 
Scotland. 
December 1978.

CRITICAL EVALUATION:

Three investigations of the solubility of NaI in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was $5 \times 10^{-5}$ S m$^{-1}$, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of NaI. However, Strack et al. noted that the solution phase showed a brownish-yellow tinge after 24 hours at 298 K which became darker with the passage of time. Free iodine was identified, and it was not found possible to prevent its formation at the high iodide concentrations involved. The effect of free iodine on the solubility of NaI is difficult to judge, but some modification of the solvent is certain and the possibility of tri-iodide formation cannot be ruled out. As it seems probable that all the solutions were contaminated to some extent with free iodine, only tentative values for NaI solubility in N-methylformamide are given. The solubilities at 298 K suggested by Strack et al. (1) (779 g/kg of solvent) and by Paul et al. (3) (795 g/kg of solvent) are in good agreement, being within 2% of each other. The value given by Berardelli et al. (2) (575 g/kg of solvent) is considerably lower than the others and is rejected on statistical grounds.

Tentative value at 298 K.

787 ± 25 g/kg of solvent.

Tentative values at 308 K and 318 K

Paul et al. (3) report solubilities at 308 K and 318 K. Since the results for solubility at 298 K given by this group have been authenticated by comparison (1), their values at higher temperature have been taken to be reliable. To check the internal consistency of these results a regression analysis was undertaken where the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. Almost perfect linearity was obtained.

308 K

870 ± 30 g/kg of solvent.

318 K

946 ± 30 g/kg of solvent.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of sodium iodide were prepared by adding excess of the powdered salt to N-methylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade sodium iodide (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N-methylformamide was purified by fractionation of the solvent over sodamide in a dry nitrogen atmosphere and had the following physical constants: B.P. 52-53 °C/1 mm; specific conductance 3-4 x 10⁻⁵ S m⁻¹; density 0.9986 g/cm³; refractive index 1.4312 at 25 °C. The solvent was stored in dark coloured bottles and kept in a dry box. Physical constants were rechecked before use.

### EXPERIMENTAL VALUES:
Solubility of sodium iodide in N-methylformamide at 25 °C

\[
57.5 \text{ g/100 g solvent}
\]

### METHODS/APPARATUS/PROCEDURE:
Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated sodium iodide solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of N-methylformamide to aqueous solution (1:5). The equivalence point remained the same(1).

### SOURCE AND PURITY OF MATERIALS:
Sodium iodide, reagent grade, was dried under high vacuum before use.
N-methylformamide (Fluka product) was purified by storing over CaO for two days before twice distilling under reduced pressure. The conductance of the N-methylformamide varied from 3.0 to 6.0 x 10⁻⁴ S m⁻¹.

December 1978.

CRITICAL EVALUATION:
Three investigations of the solubility of KCl in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was 5 x 10⁻⁵ S m⁻¹, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of KCl.

The solubilities reported at 298 K by Strack et al. (1) (20.4 g/kg of solvent) and by Berardelli et al. (2) (21.4 g/kg of solvent) are in excellent agreement. The value given by Paul et al. (3) (25.4 g/kg of solvent) is relatively high, but there seems no reason, either statistical or methodological, to reject it. (It might however be noted that Paul et al. give no details of their analytical methods). The mean of all three experimental values is therefore taken as the recommended value.

Recommended value at 298 K

22.4 ± 2.7 g/kg of solvent.

Values at other temperatures
Strack et al. (1), who measured solubilities over the temperature range 273-308 K, do not quote values at temperatures other than 298 K, but report a zero temperature coefficient of solubility. Paul et al. (3), on the other hand, who give values at 308 K and 318 K suggest that the solubility increases markedly with temperature. No tentative values for solubility are therefore recommended for temperatures other than 298 K.

University of St. Andrews,  
St. Andrews, Fife,  
Scotland.  
December 1978.

### CRITICAL EVALUATION:

Three investigations of the solubility of KBr in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was $5 \times 10^{-5}$ S m$^{-1}$, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of KBr.

The solubilities reported at 298 K by all three groups show excellent agreement, having a mean value of 101.7 g/kg of solvent, and a standard deviation of 1.0 g/kg of solvent, or 1%. This mean is taken as the recommended value.

#### Recommended value at 298 K

101.7 ± 1.0 g/kg of solvent.

#### Values at other temperatures

Strack et al. (1), who measured solubilities over the temperature range 273-308 K, do not quote values at temperatures other than 298 K, but report a linear relationship between molal solubility and temperature, with a decreasing solubility with increasing temperature. Paul et al. (3), on the other hand, who give values at 308 K and 318 K, show a slowly increasing solubility with increasing temperature. It is likely that the temperature coefficient of solubility is small, but because of these discrepancies no tentative values can be given.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of potassium bromide were prepared by adding excess of the powdered salt to N-methylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade potassium bromide (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N-methylformamide was purified by fractionation of the solvent over sodamide in a dry nitrogen atmosphere and had the following physical constants: B.P. 52-53 °C/1 mm; specific conductance 3-4 x 10<sup>-5</sup> S m<sup>-1</sup>; density 0.9986 g/cm<sup>3</sup>; refractive index 1.4312 at 25 °C. The solvent was stored in dark coloured bottles and kept in a dry box. Physical constants were rechecked before use.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

### VARIABLES:

- One temperature: 25 °C

### PREPARED BY:

J.S. McKechnie

### EXPERIMENTAL VALUES:

Solubility of potassium bromide in N-methylformamide at 25 °C

10.2 g /100 g solvent.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated potassium bromide solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimer (type Radiometer TTT1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of N-methylformamide to aqueous solution (1:5). The equivalence point remained the same(1).

**SOURCE AND PURITY OF MATERIALS:**

Potassium bromide, reagent grade, was dried under high vacuum before use. N-methylformamide (Fluka product) was purified by storing over CaO for two days before twice distilling under reduced pressure. The conductance of the N-methylformamide varied from 3.0 to 6.0 x 10⁻⁴S m⁻¹.

**ESTIMATED ERROR:**

- Solubility: ± 1%

METHOD/APPARATUS/PROCEDURE: (continuation)

As the densities were used to calculate concentrations on the molar scale the results are estimated to be accurate to within 2% on that scale, and to within 1% on the molal and mole ratio scales.

The solubilities in molal units were found to be linear functions of temperature over the range 0-35 °C. The constants A and B in the equation \( m = AT + B \) were determined for each salt by linear regression analysis. No information is given concerning the standard errors of the regression coefficients. However by comparing the solubilities quoted for direct measurements at 25 °C with those derived from the linear equations, the calculated solubilities are within 0.6 to 2.5% of those derived by direct measurement.

SOURCE AND PURITY OF MATERIALS: (continuation)

in tightly-stoppered brown glass bottles at room temperature.

The physical constants of the N-methylformamide were (literature values in parentheses):

\( n_D = 1.4305 \) [1.4300(4), 1.4310(2)]; \( p_4^2 = 1.01 \) [1.008 at 15 °C(5)]; B.Pt. = 62 °C at 6 mm. of Hg [51 °C at 1 mm. of Hg (5)].

In all cases, salts and solvent were stored and transferred in such a manner as to minimise the absorption of atmospheric moisture, presumably by the use of a dry box.

PREPARED BY:
J.S. McKechnie

EXPERIMENTAL VALUES:

Solubility of potassium bromide in N-methylformamide at 25 °C

9.95 g/100 g solvent

Within the temperature range 0-35 °C the solubilities in g/100 g of solvent, S, are given by:

\[ S = -0.012 T + 13.79 \]

where T is the absolute temperature.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
An excess of potassium bromide and 10 cm³ of N-methylformamide in a carefully stoppered test tube were placed in a constant temperature bath for 2-4 days. The test tubes were shaken several times each day. Saturation was assumed when samples taken at least one day apart gave identical concentrations, 5 cm³ samples were withdrawn with a pipette equipped with a glass wool filter over the tip, and transferred to a glass stoppered weighing bottle. The contents of the weighing bottle were diluted to 100 cm³ with water and the halide titrated by Fajan's method. To check the reliability of the method, known samples of halide salts mixed with N-methylformamide in water were analysed and the results reported as excellent. Berger and Dawson (1) also report successful analyses of halides in the presence of formamide by Fajan's method. Densities were not as accurate as the corresponding weight data since they relied on temperature dependent pipette volumes.

December 1978

CRITICAL EVALUATION:

Three investigations of the solubility of KI in N-methylformamide have been reported, all within the last fifteen years (1-3). N-methylformamide is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (4). Later, Feakins and Lawrence (5) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls, and recommended baking out containers, etc., where possible before use.

It should be noted that in two of the current solubility studies (those by Strack et al. (1) and by Paul et al. (3)), the solvent conductance was 5 x 10⁻⁵ S m⁻¹, which is as low as that reported in any investigation of this solvent. The other major difficulty which may arise in solubility measurements in N-methylformamide, namely solvate formation, has not been detected in any of the three studies of KI. However Strack et al. noted that the solution phases showed a brownish-yellow tinge after 24 hours at 298 K which became darker with the passage of time. Free iodine was identified, and it was not found possible to prevent its formation at the high iodide concentrations involved.

The effect of free iodine on the solubility of KI is difficult to judge, but some modification of the solvent is certain and the possibility of tri-iodide formation cannot be ruled out. As it seems probable that all the solutions were contaminated to some extent with free iodine, only tentative values for KI solubility in N-methylformamide are given. The solubilities at 298 K suggested by Strack et al. (1) (486 g/kg of solvent) and by Berardelli et al. (2) (496 g/kg of solvent) are in good agreement, being within 1% of each other. The value given by Paul et al. (3) (442.1 g/kg of solvent) is considerably lower than the others and is rejected on statistical grounds.

Tentative value at 298 K.

491 ± 15 g/kg of solvent.

The internal consistency of their results was good, as shown by a regression analysis taking the logarithm of the solubility as a linear function of the reciprocal of the absolute temperature. However agreement between the two sets of results at 298 K is rather poor.

The mean value of 281 g/kg of solvent would require an error bar of \( \pm 44 \) g/kg or \( \pm 15\% \) to encompass the two experimental values. The only reasonable conclusion that may be drawn from these results is that the minimum solubility of \( \text{NH}_4\text{Br} \) at 298 K is likely to be \( \geq 237 \) g/kg of solvent.

### METHOD/APPARATUS/PROCEDURE:

Saturated solutions of ammonium bromide were prepared by adding excess of the powdered salt to N-methylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

### SOURCE AND PURITY OF MATERIALS:

A.R. grade ammonium bromide (BDH) was recrystallised and dried under vacuum at 110-125 °C.

N-methylformamide was purified by fractionation of the solvent over sodamide in a dry nitrogen atmosphere and had the following physical constants: B.Pt. 52-53 °C/1 mm; specific conductance 3-4 x 10^-8 m^-2; density 0.9986 g/cm^3; refractive index 1.4312 at 25 °C. The solvent was stored in dark coloured bottles and kept in a dry box. Physical constants were rechecked before use.

### ESTIMATED ERROR:

### EXPERIMENTAL VALUES:

**Solubility of ammonium bromide in N-methylformamide at 25 °C**

23.7 g/100 g solvent

Within the temperature range 0-35 °C the solubilities in g/100 g of solvent, $S$, are given by:

$$ S = 0.000 T + 23.99 $$

where $T$ is the absolute temperature.

### METHOD/APPARATUS/PROCEDURE:

An excess of ammonium bromide and 10 cm$^3$ of N-methylformamide in a carefully stoppered test tube were placed in a constant temperature bath for 2-4 days. The test tubes were shaken several times each day. Saturation was assumed when samples taken at least one day apart gave identical concentrations. 5 cm$^3$ samples were withdrawn with a pipette equipped with a glass wool filter over the tip, and transferred to a glass stoppered weighing bottle. The contents of the weighing bottle were diluted to 100 cm$^3$ with water and the halide titrated by Fajan's method. To check the reliability of the method, known samples of halide salts mixed with N-methylformamide in water were analysed and the results reported as excellent. Berger and Dawson (1) also report successful analyses of halides in the presence of formamide by Fajan's method. Densities were not as accurate as the corresponding weight data since they relied on temperature dependent pipette volumes. As the densities were used to calculate

### SOURCE AND PURITY OF MATERIALS:

Anhydrous A.R. grade ammonium bromide was used without further purification after drying at 105 °C for 24 hours. N-methylformamide was prepared by either of two methods: the addition of methylamine to formic acid (2) or by the classical method of the addition of methylamine to ethyl formate (3). The N-methylformamide was fractionally recrystallised until the conductance reached a value of between 10$^{-1}$ (continued)

METHOD/APPARATUS/PROCEDURE: (continuation)

concentrations on the molar scale the results are estimated to be accurate to within 2% on that scale, and to within 1% on the molal and mole ratio scales.

The solubilities in molal units were found to be linear functions of temperature over the range 0-35 °C. The constants A and B in the equation m = AT + B were determined for each salt by linear regression analysis. No information is given concerning the standard errors of the regression coefficients. However by comparing the solubilities quoted for direct measurements at 25 °C with those derived from the linear equations, the calculated solubilities are within 0.6 - 2.5% of those derived by direct measurement.

SOURCE AND PURITY OF MATERIALS: (continuation)

and 10⁻² S m⁻¹. It was stored in tightly-stoppered brown glass bottles at room temperature.

The physical constants of the N-methylformamide were (literature values in parentheses):

n²⁵ = 1.4305 [1.4300(4), 1.4310(2)]; ρ²¹ = 1.01 [1.008 at 15 °C(5)]; B.Pt. = 62 °C at 6 mm of Hg [51 °C at 1 mm. of Hg(5)].

In all cases, salts and solvent were stored and transferred in such a manner as to minimise the absorption of atmospheric moisture, presumably by the use of a dry box.

REFERENCES: (continuation)

CRITICAL EVALUATION:

One investigation of the solubility of \( \text{NH}_4 \text{I} \) in N-methylformamide has been reported (1). This solvent is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (2). Later, Feakins and Lawrence (3) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use. In the current study, the solvent conductance was \( 5 \times 10^{-5} \text{ S m}^{-1} \), which is as low as that reported in any investigation of this solvent.

The solubility was measured at 298 K, 308 K and 318 K. To check the internal consistency of the results, a regression analysis was undertaken where the logarithm of the solubility was assumed to be a linear function of the reciprocal of the absolute temperature. Excellent linearity was obtained with a correlation coefficient of 0.999. However, in a parallel investigation of NaI and KI, Strack et al. (4) pointed out that iodide ion in high concentration in this solvent was liable to form free iodine in solution. No reference to this phenomenon is made by Paul et al., but because of the possibility of iodine contamination, the following values should be taken as tentative.

Tentative values

- 298 K: \( 380 \pm 12 \text{ g/kg of solvent} \)
- 308 K: \( 585 \pm 18 \text{ g/kg of solvent} \)
- 318 K: \( 821 \pm 25 \text{ g/kg of solvent} \)

CRITICAL EVALUATION:
One investigation of the solubility of MgCl₂ in N-methylformamide has been reported (1). This solvent is perhaps the most difficult of all the amide solvents to make and retain in a pure condition. A continuous rise in the conductance of the solvent with time was first reported by French and Glover (2). Later, Feakins and Lawrence (3) suggested that this might be due to the formation of methyl ammonium formate by a hydrolysis reaction at the vessel walls and recommended baking out containers, etc., where possible, before use. In the current study, the solvent conductance had a mean value of 5 x 10⁻⁴ S m⁻¹, which is an order of magnitude greater than that of solvent used by other workers, studying electrolyte solubility. An additional problem is that the investigators did not follow the recommended method for preparing anhydrous MgCl₂ (by passing dry HCl over the hydrated double salt, MgCl₂·NH₄Cl), and so the purity of the solute is not known. The reported value of the solubility at 298 K is therefore proposed only as a tentative value.

Tentative value at 298 K

88 ± 2 g/kg of solvent.

EXPERIMENTAL VALUES:

Solubility of magnesium chloride in N-methylformamide at 25 °C
8.80 g/100 g solvent

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Considerable effort was made to obtain water free solutions and all the solutions were prepared in a dry box. Saturated magnesium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was diluted with water (1:20) and the amount of dissolved halide determined by a potentiometric method using a titrimeter (type Radiometer TTT1) and, presumably, standard aqueous silver nitrate.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide. The applicability of the method was checked by increasing the ratio of N-methylformamide to aqueous solution (1:5). The equivalence point remained the same (1).

SOURCE AND PURITY OF MATERIALS:
Magnesium chloride, reagent grade, was dried under high vacuum before use.
N-methylformamide (Fluka product) was purified by storing over CaO for two days before twice distilling under reduced pressure. The conductance of the N-methylformamide varied from 3.0 to 6.0 x 10⁻⁴ S m⁻¹.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

**CRITICAL EVALUATION:**
One investigation of the solubility of LiF in N,N-dimethylformamide (DMF) has been reported (1). This solvent is readily prepared free from ionic impurities by vacuum distillation and the conductance found in this study, 0.32 - 1.50 x 10⁻⁵ S m⁻¹ is as low as has ever been reported. However, as Thomas and Rochow (2) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF₂H₂O. These authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. Again, the solvent used in this solubility study by Criss and Luksha had one of the lowest water contents so far reported (≤ 0.002% as determined by Karl Fischer titration). Solvate formation was shown to be absent in this system.

**Recommended value at 298 K**
(1.39 ± 0.18) x 10⁻³ g/kg of solvent

Solubility of lithium fluoride in N,N-dimethylformamide at 25 °C

1.39 x 10⁻⁴ g/100 g solvent

Value calculated from solubility data given as:

5.34 ± 0.69 x 10⁻⁵ mol/kg of N,N-dimethylformamide.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Saturated solutions of lithium fluoride were prepared in special Pyrex glass cells, 18 cm long and 4.5 cm in diameter. The cells were drawn out at the top in order that they could be fitted with rubber serum caps. They were supported in a water bath by a rocker which oscillated 200 times/minute through an arc of about 30°.

Solubilities were obtained by approaching equilibrium from both under- and supersaturation. In both approaches solutions were analysed daily until no further concentration changes could be detected. The solutions were analysed either by a flame photometer or by carefully evaporating to dryness and weighing the residue. In cases where both techniques were employed, the agreement was within 3%.

SOURCE AND PURITY OF MATERIALS:

Lithium fluoride was prepared by the dropwise addition of aqueous HF to an aqueous solution of lithium chloride in a polyethylene beaker. When precipitation was complete, the LiF was filtered and washed repeatedly with conductivity water, before drying at 150 °C under vacuum for 24 hours and storing in sealed vials until ready for use.

(1) Lithium fluoride; LiF; [7789-24-4]

(2) N,N-dimethylformamide; C₉H₁₄NO; [68-12-2]

SOURCE AND PURITY OF MATERIALS: (continuation)

N,N-dimethylformamide was purified by treatment with calcium hydride accompanied by vigorous stirring and then distilling under reduced pressure through a 35 cm Vigreux column. The boiling point was 68 °C at 53 mm pressure. The reported value is 79 °C at 61-62 mm (1). The specific conductance was in the range 0.32 - 1.5 x 10⁻⁵ S m⁻¹, which is in good agreement with the lowest values reported in the literature (0.6 - 18.3 x 10⁻³ S m⁻¹ (1), (2)). There was no noticeable increase in conductivity with time.

Karl Fischer titrations indicated the water content to be less than 0.002%.

## Critical Evaluation:

Three investigations of the solubility of LiCl in N,N-dimethylformamide (DMF) have been reported (1-3). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (4). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5} \text{ S m}^{-1}$ in all the investigations. However, as Thomas and Rochow (5) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.$2\text{H}_2\text{O}$. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. It should be noted that none of the three groups who studied this system report that they followed the recommended method for preparing anhydrous LiCl (by passing dry HCl over the salt). The purity of the solute is unknown.

A major problem in the determination of the solubility of LiCl in this solvent is that the equilibrium state of the solid phase is almost certainly a solvate. Paul and Sreenathan (1) isolated a white solid of composition LiCl.DMF (Li: found 6.17%, required 6.06%; Cl: found 31.03%; required 30.74%). However it is not clear from their results whether the solution was in equilibrium with this solvate, or, as seems more likely, more than one solid phase was present and no equilibrium was established. None of the other authors considers the possibility of solvate formation. The wide range of solubilities reported for LiCl (114-275 g/kg of solvent) suggests that a normal solubility equilibrium cannot be measured and no solubility value is therefore recommended.

AUXILIARY INFORMATION

METHOD/APARATUS/PROCEDURE:
Saturated solutions of lithium chloride were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen-filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade lithium chloride (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 °C/57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

J.S. McKechnie

EXPERIMENTAL VALUES:
Solubility of lithium chloride in N,N-dimethylformamide at 25 °C

11.3 g/100 g solvent

METHOD/APPARATUS/PROCEDURE:
Considerable effort was made to obtain water free solutions and all the solutions were prepared in the dry box. Saturated lithium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was collected and weighed. This solution was then diluted with water (1:10) and the amount of dissolved halide determined volumetrically by titration with standard silver nitrate using potassium chromate as indicator.
Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide.

SOURCE AND PURITY OF MATERIALS:
Lithium chloride, reagent grade, was dried under vacuum before use.
Reagent grade N,N-dimethylformamide (C. Erba RP) was purified by fractional distillation under reduced pressure (2 mm Hg). The final product had a specific conductance of 3 x 10⁻⁵ S m⁻¹.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

REFERENCES:
COMPONENTS:
(1) Lithium chloride; LiCl; [7447-41-8]
(2) N,N-dimethylformamide; C₉H₁₂NO; [68-12-2]

EXPERIMENTAL VALUES:

Solubility of lithium chloride in N,N-dimethylformamide at 25 °C

27.5 g/100 g solvent

PREPARED BY:
J.S. McKechnie

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of lithium chloride were prepared by adding the salt in small quantities to 10 cm³ of N,N-dimethylformamide contained in Pyrex test tubes, until an appreciable amount remained undissolved. The tubes were then sealed and fixed to a shaft immersed and arranged to rotate in a thermostatted water-bath at 25 °C. The temperature was maintained using a toluene regulator. After 24-30 hours of thorough mixing the seal was broken in a dry box and the slurry rapidly filtered under dry conditions. From a known quantity of the solution the metal was estimated and the solubility of the salt determined. No details of the analytical methods used were given.

SOURCE AND PURITY OF MATERIALS:
Purity of lithium chloride was not stated. N,N-dimethylformamide (J.T. Baker analysed) was stored over A.R. anhydrous sodium carbonate for 48 hours with occasional shaking. The solvent was then decanted and distilled through a short column. The middle fraction distilling at 149-151 °C/745 mm was collected and redistilled under a reduced pressure of 35 mm in an atmosphere of dry nitrogen. The specific conductance of this N,N-dimethylformamide measured 3 x 10⁻⁵ S m⁻¹ at 25 °C.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.1 °C (author)

December 1978.

CRITICAL EVALUATION:
Two investigations of the solubility of LiBr in N,N-dimethylformamide (DMF) have been reported (1-2). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5}$ S m⁻¹ in all the investigations. However, as Thomas and Rochow (3) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF₂H₂O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

Neither of the groups studying the solubility of LiBr report examining the solid in equilibrium with the solution with a view to determining whether solvate formation was occurring. The discrepant nature of the results (166 g/kg of solvent (1) and 251 g/kg of solvent (2)) suggests that a proper equilibrium might not have been established. No recommendation is made for a value of the solubility.

December 1978.

CRITICAL EVALUATION:
One investigation of the solubility of NaF in N,N-dimethylformamide (DMF) has been reported (1). This solvent is readily prepared free from ionic impurities by vacuum distillation and the conductance found in this study, 0.32-1.50 x 10⁻⁵ S m⁻¹ is as low as has ever been reported. However, as Thomas and Rochow (2) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF·2H₂O. These authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. Again, the solvent used in this solubility study by Criss and Luksha had one of the lowest water contents so far reported (< 0.002% as determined by Karl Fischer titration). Solvate formation was shown to be absent in this system.

Recommended value at 298 K

(1.96 ± 0.14) x 10⁻³ g/kg of solvent.

EXPERIMENTAL VALUES:

Solubility of sodium fluoride in N,N-dimethylformamide at 25 °C

\[ 1.96 \times 10^{-4} \text{ g/100 g solvent} \]

Value calculated from solubility data given as:

\[ 4.68 \pm 0.34 \times 10^{-5} \text{ mol/kg N,N-dimethylformamide} \]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Saturated solutions of sodium fluoride were prepared in special Pyrex glass cells, 18 cm long and 4.5 cm in diameter. The cells were drawn out at the top in order that they could be fitted with rubber serum caps. They were supported in a water bath by a rocker which oscillated 200 times/minute through an arc of about 30°.

Solubilities were obtained by approaching equilibrium from both under- and supersaturation. In both approaches solutions were analysed daily until no further concentration changes could be detected. The solutions were analysed either by a flame photometer or by carefully evaporating to dryness and weighing the residue. In cases where both techniques were employed, the agreement was within 3%. (continued)

SOURCE AND PURITY OF MATERIALS:

Sodium fluoride was prepared by the dropwise addition of aqueous HF to an aqueous solution of sodium chloride in a polyethylene beaker. When precipitation was complete, the NaF was filtered and washed repeatedly with conductivity water, before drying at 150 °C under vacuum for 24 hours and storing in sealed vials until ready for use.

Criss, C.M.; Luksha, E. J. Phys. Chem. 1968, 72, 2966-2920

SOURCE AND PURITY OF MATERIALS: (continuation)

N,N-dimethylformamide was purified by treatment with calcium hydride accompanied by vigorous stirring and then distilling under reduced pressure through a 35 cm Vigreux column. The boiling point was 68 °C at 53 mm pressure. The reported value is 79 °C at 61-62 mm (1). The specific conductance was in the range 0.32 - 1.5 x 10⁻⁵ S m⁻¹, which is in good agreement with the lowest values reported in the literature (0.6 - 18.3 x 10⁻⁵ S m⁻¹ (1), (2)). There was no noticeable increase in conductivity with time.

Karl Fischer titrations indicated the water content to be less than 0.002%.

December 1978.

CRITICAL EVALUATION:
Three investigations of the solubility of NaCl in N,N-dimethylformamide (DMF) have been reported (1-3). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (4). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below 3 x 10⁻⁵ S m⁻¹ in all the investigations. However, as Thomas and Rochow (5) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.₂H₂O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. The most anhydrous solvent used in these studies of NaCl solubility is likely to have been that of Criss and Luksha (3) who found a water content of 0.002% by Karl Fischer titration. The other major difficulty which may arise in solubility measurements in DMF, namely solvate formation, was shown to be absent in this particular system.

The results of the four measurements (all at a single temperature, 298 K) are in good agreement, falling in the range 0.36 - 0.50 g/kg of solvent. The lowest value, which was obtained with the driest solvent and very careful analytical techniques is taken as the recommended value.

Recommended value at 298 K

0.36 ± 0.01 g/kg of solvent.

December 1978.

CRITICAL EVALUATION:
Three investigations of the solubility of NaI in N,N-dimethylformamide (DMF) have been reported (1-3). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (4). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below \(3 \times 10^{-5} \text{ S m}^{-1}\) in all the investigations. However, as Thomas and Rochow (5) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.\(2\text{H}_2\text{O}\). The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

In the case of NaI, the possible complication of solvate formation was excluded by Paul and Sreenathan (1) who analysed the solid phase in equilibrium with the solution. However the results of these solubility studies show little agreement, even if the very high value suggested by the duPont report is excluded. No convincing explanation of the wide range of values from the remaining three groups (37.2 - 80.5 g/kg of solvent) can be given, but it might be noted that iodide ion has been found to react with DMF, albeit to a limited extent, producing a yellow tinge in solutions of KI (6). No tentative value is recommended.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of sodium iodide were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10°C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade sodium iodide (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 °C/57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

2. N,N-dimethylformamide; C₉H₁₃NO; [68-12-2]

**ORIGINAL MEASUREMENTS:**

Pistoia, G.; Pecci, G.; Scrosati, B. Ric. Sc. 1967, 37, 1167-1172

**VARIABLES:**

One temperature: 25 °C

**PREPARED BY:**

J.S. McKechnie

**EXPERIMENTAL VALUES:**

Solubility of sodium iodide in N,N-dimethylformamide at 25 °C

6.35 g/100 g solvent

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water free solutions and all the solutions were prepared in the dry box. Saturated sodium iodide solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostated bath. With the aid of a syphon provided with a terminal G-3 gouch, an aliquot of the saturated solution was collected and weighed. This solution was then diluted with water (1:10) and the amount of dissolved halide determined volumetrically by adding an excess of standard silver nitrate and back titrating against standard ammonium thiocyanate using ferric alum as indicator.

Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide.

**SOURCE AND PURITY OF MATERIALS:**

Sodium iodide, reagent grade, was dried under vacuum before use.

Reagent grade N,N-dimethylformamide (C. Erba RP) was purified by fractional distillation under reduced pressure (2 mm Hg). The final product had a specific conductance of 3 x 10⁻⁵ S m⁻¹.

**ESTIMATED ERROR:**

Solubility ± 1%

Temperature ± 0.05 °C (author)

**REFERENCES:**

EXPERIMENTAL VALUES:

Solubility of sodium iodide in N,N-dimethylformamide at 25 °C

3.72 g/100 g solvent

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Saturated solutions of sodium iodide were prepared by adding the salt in small quantities to 10 cm³ of N,N-dimethylformamide contained in Pyrex test tubes, until an appreciable amount remained undissolved. The tubes were then sealed and fixed to a shaft immersed and arranged to rotate in a thermostatted water-bath at 25 °C. The temperature was maintained using a toluene regulator. After 24-30 hours of thorough mixing the seal was broken in a dry box and the slurry rapidly filtered under dry conditions. From a known quantity of the solution the metal was estimated and the solubility of the salt determined. No details of the analytical methods used were given.

SOURCE AND PURITY OF MATERIALS:

Purity of sodium iodide was not stated.
N,N-dimethylformamide (J.T.Baker analysed) was stored over A.R. anhydrous sodium carbonate for 48 hours with occasional shaking. The solvent was then decanted and distilled through a short column. The middle fraction distilling at 149-151 °C/745 mm was collected and redistilled under a reduced pressure of 35 mm in an atmosphere of dry nitrogen. The specific conductance of this N,N-dimethylformamide measured 3 x 10⁻⁵ S m⁻¹ at 25 °C.

ESTIMATED ERROR:

Solubility ± 1%
Temperature ± 0.1 °C (author)

REFERENCES:
CRITICAL EVALUATION:
One investigation of the solubility of NaCN in N,N-dimethylformamide (DMF) has been reported (1). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (2). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5}$ S m$^{-1}$ in all the investigations. However, as Thomas and Rochow (3) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.$2H_2O$. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

The solubilities reported in the duPont study (2) (7.6 g/kg of solvent) and by Paul and Sreenathan (1) (187.6 g/kg of solvent) are so far apart that it is difficult to suggest a reason. One factor which may be of importance is the reactivity of N,N-dimethylformamide with cyanide ions which, at least at higher temperatures, gives rise to the formation of HCN, CO and the metal dimethylamine complex (1). No solvate is formed by NaCN with this solvent (1).

It is therefore not possible to recommend a value for the solubility of this salt.

CRITICAL EVALUATION:
The only investigation of the solubility of NaCNO in N,N-dimethylformamide (DMF) so far reported has been a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) (1). No details are given of either the analytical methods used nor of the purity of the solvent. At best the duPont value can be recommended as a tentative value. Note should be taken, however, of the very large discrepancy between the duPont value for the solubility of NaCN in this solvent and that reported by Paul and Sreenathan (2).

Tentative value at 298 K
0.5 ± 0.1 g/kg of solvent.

**CRITICAL EVALUATION:**

Three investigations of the solubility of NaCNS in N,N-dimethylformamide (DMF) have been reported (1-3). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (4). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below 3 x 10⁻⁵ S m⁻¹ in all the investigations. However, as Thomas and Rochow (5) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF₂H₂O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

A major problem in the determination of the solubility of NaCNS in this solvent is that the true equilibrium state of the solid phase is almost certainly a solvate. Paul and Sreenathan (1) isolated a colourless solid of composition NaCNS. DMF (Na: found 15.17%, required 14.93%; S: found 21.03%, required 20.77%). However it is not clear from their results whether the solution was in equilibrium with the solvate or whether both solvate and salt solid phases were present. None of the other authors considered the possibility of solvate formation. However the solubilities reported by three of the groups show good consistency, all falling within the range 292-299 g/kg of solvent. The mean of these results is therefore recommended as a tentative value.

Tentative value at 298 K
295 ± 4 g/kg of solvent.

CRITICAL EVALUATION:

Five investigations of the solubility of KCl in N,N-dimethylformamide (DMF) have been reported (1-5). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (6). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5}$ S m$^{-1}$ in all the investigations. However, as Thomas and Rochow (7) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.$2\text{H}_2\text{O}$. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. The most anhydrous solvent used in these studies of KCl solubility is likely to have been that of Criss and Luksha (4) who found a water content of $\leq 0.002\%$ by Karl Fischer titration. The other major difficulty which may arise in solubility measurements in DMF, namely solvate formation, was shown to be absent in this particular system.

The six solubilities reported at 298 K fall into two groups. The value of 0.50 g/kg of solvent found by Paul and Sreenathan (1) and by Paul et al. (5) is supported by the duPont study. A considerably lower value was determined by the three other groups. Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Alexander et al. (3) with the molal solubilities of the other two groups. However the latter result is certainly consistent with those of Criss and Luksha (4) and Pistoia et al. (2). Taking into account the known low water content of the solvent used by Criss and Luksha, the recommended value is taken as the mean of the solubilities reported by Criss and Luksha and by Pistoia et al.

**Recommended value at 298 K**

$0.185 \pm 0.020$ g/kg of solvent.

**Values at other temperatures**

Paul et al. (5) also measured the solubility of KCl at 308 K and 318 K. Since their value at 298 K has been rejected, no recommended or tentative value is given at these temperatures. However it might be noted that the temperature coefficient of solubility appears to be small and negative.

Solubility of potassium chloride in N,N-dimethylformamide at 25 °C
0.017 g/100 g solvent

Value calculated from solubility data given as:

\[ 2.28 \pm 0.07 \times 10^{-3} \text{ mol/kg N,N-dimethylformamide} \]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of potassium chloride were prepared in special Pyrex glass cells, 18 cm long and 4.5 cm in diameter. The cells were drawn out at the top in order that they could be fitted with rubber serum caps. They were supported in a water bath by a rocker which oscillated 200 times/minute through an arc of about 30°.

Solubilities were obtained by approaching equilibrium from both under- and supersaturation. In both approaches solutions were analysed daily until no further concentration changes could be detected. The solutions were analysed either by a flame photometer or by carefully evaporating to dryness and weighing the residue. In cases where both techniques were employed, the agreement was within 3%.

SOURCE AND PURITY OF MATERIALS:
Reagent grade potassium chloride was further purified by double recrystallisation from conductivity water. The salt was stored at 400 °C until ready for use.

ESTIMATED ERROR:
Solubility ± 3%
Temperature ± 0.05 °C (author)

ORIGINAL MEASUREMENTS:

SOURCE AND PURITY OF MATERIALS; (continuation)
N,N-dimethylformamide was purified by treatment with calcium hydride accompanied by vigorous stirring and then distilling under reduced pressure through a 35 cm Vigreux column. The boiling point was 68 °C at 53 mm pressure. The reported value is 79 °C at 61-62 mm (1). The specific conductance was in the range 0.32 - 1.5 x 10⁻⁵ S m⁻¹, which is in good agreement with the lowest values reported in the literature (0.6 - 18.3 x 10⁻⁵ S m⁻¹ (1), (2)). There was no noticeable increase in conductivity with time.

Karl Fischer titrations indicated the water content to be less than 0.002%.

0.02 g/100 g solvent

**METHOD/APPARATUS/PROCEDURE:**

Considerable effort was made to obtain water free solutions and all the solutions were prepared in the dry box. Saturated potassium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gouch, an aliquot of the saturated solution was collected and weighed. This solution was then diluted with water (1:10) and the amount of dissolved halide determined volumetrically by titration with standard silver nitrate using potassium chromate as indicator. Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide.

**SOURCE AND PURITY OF MATERIALS:**

Potassium chloride, reagent grade, was dried under vacuum before use. Reagent grade N,N-dimethylformamide (C. Erba RP) was purified by fractional distillation under reduced pressure (2 mm Hg). The final product had a specific conductance of 3 x 10⁻⁵ S m⁻¹.

**ESTIMATED ERROR:**

Solubility ± 1%

Temperature ± 0.05 °C (author)

ORIGINAL MEASUREMENTS:

VARIABLES:

One temperature: 25 °C

PREPARED BY:

J.S. McKechnie

EXPERIMENTAL VALUES:

Solubility of potassium chloride in N,N-dimethylformamide at 25 °C

0.15 g/1000 cm³ of saturated solution.

Value calculated from solubility product data given as:

\[ \log(K_s \text{g/mol dm}^{-3}) = -5.4 \]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Saturated solutions of potassium chloride were prepared by shaking the solid with solvent in a stoppered flask at 35 °C for 24 hours. The flask was then shaken for a further 24 hours at 25 °C. The liquid phase was analysed for halide potentiometrically using silver concentration cells with a tetraethylammonium picrate salt bridge. The cells were wrapped in aluminium foil and immersed in a 25 °C thermostat and stirred magnetically, as standard 0.01 mol dm⁻³ silver nitrate was added. The emf was measured on a Radiometer pH meter (type PHM 22r).

It was established early in the work that effectively the same results were obtained no matter whether measurements were made in the dark on freshly prepared solutions, on solutions exposed to the atmosphere for 30 minutes, or on solutions kept under dry nitrogen during preparation and titration.

The usual procedure was to titrate 0.01 mol dm⁻³ AgNO₃ solution into a half-cell containing the silver were immersed in 20 cm³ of 0.01 mol dm⁻³ potassium chloride in DMF. The reference half-cell was a silver wire in 0.01 mol dm⁻³ AgNO₃ in the same solvent.

SOURCE AND PURITY OF MATERIALS:

A.R. grade potassium chloride was used without further preparation.

N,N-dimethylformamide was dried with Type 4A molecular sieves and fractionated twice under a reduced pressure of dry nitrogen. It was stored over molecular sieves in dark bottles and was used within 7 days of purification.

The stock solution of 0.01 mol dm⁻³ AgNO₃ for the potentiometric titrations was also stored in a light proof container.

ESTIMATED ERROR:

Solubility ± 2%

Temperature ± 0.1 °C (compiler)

J.S. McKechnie

**EXPERIMENTAL VALUES:**

Solubility of potassium chloride in N,N-dimethylformamide at 25 °C

0.05 g/100 g solvent

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of potassium chloride were prepared by adding the salt in small quantities to 10 cm³ of N,N-dimethylformamide contained in Pyrex test tubes, until an appreciable amount remained undissolved. The tubes were then sealed and fixed to a shaft immersed and arranged to rotate in a thermostatted water-bath at 25 °C. The temperature was maintained using a toluene regulator. After 24-30 hours of thorough mixing the seal was broken in a dry box and the slurry rapidly filtered under dry conditions. From a known quantity of the solution the metal was estimated and the solubility of the salt determined. No details of the analytical methods used were given.

**SOURCE AND PURITY OF MATERIALS:**

Purity of potassium chloride was not stated. N,N-dimethylformamide (J.T.Baker analysed) was stored over A.R. anhydrous sodium carbonate for 48 hours with occasional shaking. The solvent was then decanted and distilled through a short column. The middle fraction distilling at 149-151 °C/745 mm was collected and redistilled under a reduced pressure of 35 mm in an atmosphere of dry nitrogen. The specific conductance of this N,N-dimethylformamide measured 3 x 10⁻⁵ S m⁻¹ at 25 °C.

**ESTIMATED ERROR:**

Solubility ± 10%
Temperature ± 0.1 °C (author)

**REFERENCES:**

December 1978.

CRITICAL EVALUATION:

Three investigations of the solubility of KBr in N,N-dimethylformamide (DMF) have been reported (1-3). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below 3 x 10⁻⁵ S m⁻¹ in all the investigations. However, as Thomas and Rochow (4) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF₂H₂O. The latter authors examined a number of chemical treatments but concluded that some water always remained in the solvent.

None of the groups studying the solubility of KBr report analysing the solid in equilibrium with the solution in order to exclude the possible complication of solvate formation. The value of the molar solubility determined by Alexander et al. (2) cannot be directly compared with the molal solubilities of the other two groups. However since the solubility of this salt is rather low and the density of the solvent is close to unity the discrepancy between molal and molar values is unlikely to be large. This suggests that the solubility reported by Pistoia et al. (1) is a reasonable estimate and that the very low value of Paul et al. (3) should be rejected.

Recommended value at 298 K

8.20 ± 0.50 g/kg of solvent

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of potassium bromide were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade potassium bromide (BDH) was recrystallised and dried under vacuum at 110-125 °C.

N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 ºC/57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

December 1978.

CRITICAL EVALUATION:
Four investigations of the solubility of KI in N,N-dimethylformamide (DMF) have been reported (1-4). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (5). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below 3 \times 10^{-5} \text{S m}^{-1} in all the investigations. However, as Thomas and Rochow (6) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.2H₂O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

In the case of KI, the possible complication of solvate formation was excluded by Paul and Sreenathan (1) who analysed the solid phase in equilibrium with the solution. However the results of these solubility studies show little agreement. Alexander et al. (3) found that some oxidation of the iodide ion always occurred and this gave the solution a yellow tinge. Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by the latter authors with the molal solubilities of the other groups. However the value of Alexander et al. (295 g/dm³ of saturated solution) is likely to fall between the central values of Paul et al. (4) (296 g/kg of solvent and of the duPont study (5) (250 g/kg of solvent). If the high value of Pistoia et al. (2) and the low value of Paul and Sreenathan (1) are excluded, the mean of the remaining values appears to be a reasonable estimate of the solubility.

Tentative value at 298 K

\[273 \pm 23 \text{ g/kg of solvent}\]

#### METHOD/APPARATUS/PROCEDURE:

Not stated

#### SOURCE AND PURITY OF MATERIALS:

Not stated.

#### ESTIMATED ERROR:

#### REFERENCES:
### COMPONENTS:

1. Potassium thiocyanate; KCNS; [333-20-2]
2. N,N-dimethylformamide; \( \text{C}_3\text{H}_7\text{NO} \); [68-12-2]

### EVALUATOR:

C.A. Vincent,
Department of Chemistry,
University of St. Andrews,
St. Andrews, Fife,
Scotland.

December 1978.

### CRITICAL EVALUATION:

Two investigations of the solubility of KCNS in N,N-dimethylformamide (DMF) have been reported (1–2). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (3). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below \( 3 \times 10^{-5} \text{ S m}^{-1} \) in all the investigations. However, as Thomas and Rochow (4) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.\( \text{H}_2\text{O} \). The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

A major problem in the determination of the solubility of KCNS in this solvent is that the equilibrium state of the solid phase is almost certainly a solvate. Paul and Sreenathan (1) isolated a colourless solid of composition KCNS.DMF (K: found 23.42%, required 22.94%; S 19.31%, required 18.83%). However it is not clear from their results whether the solution was in equilibrium with this solvate, or, as seems more likely, more than one solid phase was present and no equilibrium was established. None of the other authors considered the possibility of solvate formation. The wide range of solubilities reported for KCNS (159.7 – 400.7 g/kg of solvent) suggests that a normal solubility equilibrium cannot be measured and no solubility value is therefore recommended.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**
Saturated solutions of potassium thiocyanate were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transfer of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**
A.R. grade potassium thiocyanate (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 °C/57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

**ESTIMATED ERROR:**
- Solubility ± 1%
- Temperature ± 0.05 °C (author)

**REFERENCES:**
**COMPONENTS:**

1. Potassium thiocyanate; KCNS; [333-20-0]
2. N,N-dimethylformamide; C₈H₁₁NO; [68-12-2]

**VARIABLES:**

One temperature: 25 °C

**PREPARED BY:**

J.S. McKechnie

**EXPERIMENTAL VALUES:**

Solubility of potassium thiocyanate in N,N-dimethylformamide at 25 °C

16.0 g/100 g solvent

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of potassium thiocyanate were prepared by adding the salt in small quantities to 10 cm³ of N,N-dimethylformamide contained in Pyrex test tubes, until an appreciable amount remained undissolved. The tubes were then sealed and fixed to a shaft immersed and arranged to rotate in a thermostatted water-bath at 25 °C. The temperature was maintained using a toluene regulator. After 24-30 hours of thorough mixing the seal was broken in a dry box and the slurry rapidly filtered under dry conditions. From a known quantity of the solution the metal was estimated and the solubility of the salt determined. No details of the analytical methods used were given.

**SOURCE AND PURITY OF MATERIALS:**

Purity of potassium thiocyanate was not stated. N,N-dimethylformamide (J.T.Baker analysed) was stored over A.R. anhydrous sodium carbonate for 48 hours with occasional shaking. The solvent was then decanted and distilled through a short column. The middle fraction distilling at 149-151 °C/745 mm was collected and redistilled under a reduced pressure of 35 mm in an atmosphere of dry nitrogen. The specific conductance of this N,N-dimethylformamide measured 3 x 10⁻⁵ S m⁻¹ at 25 °C.

**ESTIMATED ERROR:**

Solubility ± 1%

Temperature ± 0.1 °C (author)

**REFERENCES:**
COMPONENTS:

(1) Caesium chloride; CsCl; [7647-17-8]
(2) N,N-dimethylformamide; C₃H₇NO; [68-12-2]

December 1978.

CRITICAL EVALUATION:

Two investigations of the solubility of CsCl in N,N-dimethylformamide (DMF) have been reported (1-2). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5}$ S m$^{-1}$ in all the investigations. However, as Thomas and Rochow (3) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.2H₂O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. The most anhydrous solvent used in these studies of CsCl solubility is likely to have been that of Criss and Luksha (2) who found a water content of $\leq 0.002\%$ by Karl Fischer titration. The other major difficulty which may arise in solubility measurements in DMF, namely solvate formation, was shown to be absent in this particular system.

Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Alexander et al. (1) with the molal solubility of Criss and Luksha (2). However the two results would seem to be consistent. The recommended value is taken to be that of the latter authors who are known to have used particularly pure solvent.

**Recommended value at 298 K**

$0.52 \pm 0.01$ g/kg of solvent.

**EXPERIMENTAL VALUES:**

Solubility of caesium chloride in N,N-dimethylformamide at 25 °C

0.052 g/100 g solvent

Value calculated from solubility date given as:

\[ 3.06 \pm 0.02 \times 10^{-3} \text{ mol/kg N,N-dimethylformamide} \]

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of caesium chloride were prepared in special Pyrex glass cells, 18 cm long and 4.5 cm in diameter. The cells were drawn out at the top in order that they could be fitted with rubber serum caps. They were supported in a water bath by a rocker which oscillated 200 times/minute through an arc of about 30°.

Solubilities were obtained by approaching equilibrium from both under- and supersaturation. In both approaches solutions were analysed daily until no further concentration changes could be detected. The solutions were analysed either by a flame photometer or by carefully evaporating to dryness and weighing the residue. In cases where both techniques were employed, the agreement was within 3%.

**SOURCE AND PURITY OF MATERIALS:**

Caesium chloride (Henley and Co., 99.95% pure) was used without further purification, except for the removal of water by drying in an air oven with the temperature being gradually raised to about 600 °C over a period of 24 hours.

The salt was stored at 400 °C until ready for use.

**ESTIMATED ERROR:**

Solubility ± 1%

Temperature ± 0.05 °C (author)

**REFERENCES:**

(continued)
COMPONENTS:
(1) Caesium chloride; CsCl; [7647-17-8]
(2) N,N-dimethylformamide; C₇H₁₁NO; [68-12-2]

SOURCE AND PURITY OF MATERIALS: (continuation)

N,N-dimethylformamide was purified by treatment with calcium hydride accompanied by vigorous stirring and then distilling under reduced pressure through a 35 cm Vigreux column. The boiling point was 68 °C at 53 mm pressure. The reported value is 79 °C at 61-62 mm (1). The specific conductance was in the range 0.32 - 1.5 \times 10^{-5} \text{ S m}^{-1}, which is in good agreement with the lowest values reported in the literature (0.6 - 18.3 \times 10^{-5} \text{ S m}^{-1} (1), (2)). There was no noticeable increase in conductivity with time.

Karl Fischer titrations indicated the water content to be less than 0.002%.

VARIABLES:

One temperature: 25 °C

PREPARED BY:
J.S. McKechnie

EXPERIMENTAL VALUES:

Solubility of caesium bromide in N,N-dimethylformamide at 25 °C

4.76 g/1000 cm³ of saturated solution

Value calculated from solubility product data given as:

\[
\log(K_s/\text{mol dm}^{-3}) = -3.3
\]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of caesium bromide were prepared by shaking the solid with solvent in a stoppered flask at 35 °C for 24 hours. The flask was then shaken for a further 24 hours at 25 °C. The liquid phase was analysed for halide potentiometrically using silver concentration cells with a tetraethylammonium picrate salt bridge. The cells were wrapped in aluminium foil and immersed in a 25 °C thermostat and stirred magnetically, as standard 0.01 mol dm⁻³ silver nitrate was added. The emf was measured on a Radiometer pH meter (type PHM 22r). It was established early in the work that effectively the same results were obtained no matter whether measurements were made in the dark on freshly prepared solutions, on solutions exposed to the atmosphere for 30 minutes, or on solutions kept under dry nitrogen during preparation and titration.

The usual procedure was to titrate 0.01 mol dm⁻³ AgNO₃ solution into a half-cell containing the silver wire immersed in 20 cm³ of 0.01 mol dm⁻³ caesium bromide in DMF. The reference half-cell was a silver wire in 0.01 mol dm⁻³ AgNO₃ in the same solvent.

SOURCE AND PURITY OF MATERIALS:
A.R. grade caesium bromide was used without further purification.
DMF was dried with Type 4A molecular sieves and fractionated twice under a reduced pressure of dry nitrogen. It was stored over molecular sieves in dark bottles and was used within 7 days of purification.
The stock solution of 0.01 mol dm⁻³ AgNO₃ for the potentiometric titrations was also stored in a light proof container.

December 1978.

**CRITICAL EVALUATION:**

Two investigations of the solubility of NH$_4$Cl in N,N-dimethylformamide (DMF) have been reported (1-2). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (3). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below $3 \times 10^{-5}$ S m$^{-1}$ in all the investigations. However, as Thomas and Rochow (4) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF$_2$H$_2$O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

In the case of NH$_4$Cl, the possible complication of solvate formation was excluded by Paul and Sreenathan (1) who analysed the solid phase in equilibrium with the solution. However the results of these solubility studies show little agreement, falling within a wide range of values (0.5 - 3.7 g/kg of solvent). No explanation of such inconsistent results can be offered and no recommended value is given.

CRITICAL EVALUATION:
One investigation of the solubility of \( \text{NH}_4\text{Br} \) in \( N,N\)-dimethylformamide (DMF) has been reported (1). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (2). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below \( 3 \times 10^{-5} \text{ S m}^{-1} \) in all the investigations. However, as Thomas and Rochow (3) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.\( \text{H}_2\text{O} \). The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

Agreement between the two reported solubilities is rather poor. In neither case are details given of the analytical methods used. While it might be argued that more weight should be given to the results of Paul et al., it should be noted that solubilities in DMF determined by this group are almost always higher than those found by other workers. In the case of \( \text{NH}_4\text{Br} \) it has therefore been decided to recommend as a tentative value the mean between the two reported solubilities.

Tentative value at 298 K

\[ 147 \pm 20 \text{ g/kg of solvent} \]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions of ammonium bromide were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostating. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

SOURCE AND PURITY OF MATERIALS:
A.R. grade ammonium bromide (BDH) was recrystallised and dried under vacuum at 110-125 °C.
N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 °C/ 57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

ESTIMATED ERROR:
Solubility ± 1%
Temperature ± 0.05 °C (author)

REFERENCES:
COMPONENTS:

Scotland.
December 1978.

CRITICAL EVALUATION:
One investigation of the solubility of \( \text{NH}_4\text{I} \) in N,N-dimethylformamide (DMF) has been reported (1). This solvent is readily prepared free from ionic impurities by vacuum distillation and the conductance of the solvent was below \( 3 \times 10^{-5} \text{ S m}^{-1} \) in this study. However as Thomas and Rochow (2) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.\( \text{H}_2\text{O} \). The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent. In this study no analysis of the solid phase in contact with the solution is reported, so it is not possible to exclude the possibility of solvate formation.

### PREPARED BY:

J.S. McKechnie

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of ammonium iodide were prepared by adding excess of the powdered salt to N,N-dimethylformamide (15-20 g) in Pyrex tubes (15 x 2.5 cm) and preheating to 10 °C above the required temperature of the bath prior to final thermostatting. The attainment of the equilibrium was checked by intermittent analyses. The solutions were then filtered under nitrogen and analysed for halide. No details of analytical methods were given. Transference of material, as far as possible, was carried out in a nitrogen filled dry box. Measurements were made in triplicate.

**SOURCE AND PURITY OF MATERIALS:**

A.R. grade ammonium iodide (BDH) was recrystallised and dried under vacuum at 110-125 °C.

N,N-dimethylformamide (Riedel Pure) was dried over A.R. anhydrous sodium carbonate for 24 hours before distilling under reduced pressure. The fraction boiling at 73 °C/57 mm was collected and had the following physical constants: density 0.9442 g/cm³; specific conductance 2.5 x 10⁻⁵ S m⁻¹ at 25 °C. The solvent was freshly distilled for each experiment.

**ESTIMATED ERROR:**

Solubility ± 1%
Temperature ± 0.05 °C (author)

**REFERENCES:**
COMPONENTS:
(1) Ammonium thiocyanate; NH$_4$CNS; [1762-95-4]
(2) N,N-dimethylformamide; C$_3$H$_7$NO; [68-12-2]

EVALUATOR:
C.A. Vincent,
Department of Chemistry,
University of St. Andrews,
St. Andrews, Fife.
Scotland.
December 1978.

CRITICAL EVALUATION:
Two investigations of the solubility of NH$_4$CNS in N,N-dimethylformamide (DMF) have been reported (1-2). In addition results from a 'semiquantitative' study by the Industrial Chemicals Department of E.I. duPont de Nemours and Co. (Inc.) have been published (3). This solvent is readily prepared free from ionic impurities by vacuum distillation, and the conductance of the solvent was below 3 x 10$^{-5}$ S m$^{-1}$ in all the investigations. However, as Thomas and Rochow (4) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF.2H$_2$O. The latter authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

A major problem in the determination of the solubility of NH$_4$CNS in this solvent is that the true equilibrium state of the solid phase is almost certainly a solvate. Paul and Sreenathan (1) isolated a colourless solvate of composition NH$_4$CNS.DMF (S: found 21.04%, required 21.44%). However it is not clear from their results whether the solution was in equilibrium with the solvate or whether both solvate and salt solid phases were present. None of the other authors considered the possibility of solvate formation. However the solubilities reported by two of the groups show good consistency and the mean of these two results is recommended as a tentative value.

Tentative value at 298 K

154 $\pm$ 2 g/kg of solvent.

Paul, R.C.; Sreenathan, B.R.

**VARIABLES:**

One temperature: 25 °C

**EXPERIMENTAL VALUES:**

Solubility of ammonium thiocyanate in N,N-dimethylformamide at 25 °C

13.4 g/100 g solvent.

**METHOD/APPARATUS/PROCEDURE:**

Saturated solutions of ammonium thiocyanate were prepared by adding the salt in small quantities to 10 cm³ of N,N-dimethylformamide contained in Pyrex test tubes, until an appreciable amount remained undissolved. The tubes were then sealed and fixed to a shaft immersed and arranged to rotate in a thermostatted water-bath at 25 °C. The temperature was maintained using a toluene regulator. After 24-30 hours of thorough mixing the seal was broken in a dry box and the slurry rapidly filtered under dry conditions. From a known quantity of the solution the metal was estimated and the solubility of the salt determined. No details of the analytical methods used were given.

**SOURCE AND PURITY OF MATERIALS:**

Purity of ammonium thiocyanate was not stated. N,N-dimethylformamide (J.T.Baker analysed) was stored over A.R. anhydrous sodium carbonate for 48 hours with occasional shaking. The solvent was then decanted and distilled through a short column. The middle fraction distilling at 149-151 °C/745 mm was collected and redistilled under a reduced pressure of 35 mm in an atmosphere of dry nitrogen. The specific conductance of this N,N-dimethylformamide measured 3 x 10⁻⁵ S m⁻¹ at 25 °C.

**ESTIMATED ERROR:**

Solubility ± 1%

CRITICAL EVALUATION:

Two investigations of the solubility of MgCl$_2$ in N,N-dimethylformamide (DMF) have been reported (1-2). This solvent is readily prepared free from ionic impurities by vacuum distillation and the conductance of the solvent was below $3 \times 10^{-5}$ S m$^{-1}$ in both investigations. However, as Thomas and Rochow (3) have pointed out, distillation is an ineffective method for removing water from DMF, mainly because of the existence of aquo-complexes such as DMF. 2H$_2$O. These last authors examined a number of chemical treatments, but concluded that some water always remained in the solvent.

A major problem in the determination of the solubility of MgCl$_2$ in this solvent is that the equilibrium state of the solid phase is almost certainly a solvate. Paul and Sreenathan (1) isolated solids of composition MgCl$_2$. 2 DMF and MgCl$_2$. DMF. However it is not clear from their results whether or not the solution was in equilibrium with these solvates. Such an uncertainty makes it impossible to recommend a value for the solubility of this salt.

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**
Considerable effort was made to obtain water free solutions and all the solutions were prepared in the dry box. Saturated magnesium chloride solutions were prepared by dissolving excess of the halide in about 20-25 cm³ of solvent contained in a 50 cm³ Pyrex flask with a standard taper joint. The solution was then stirred for three or more days in a thermostatted bath. With the aid of a syphon provided with a terminal G-3 gooch, an aliquot of the saturated solution was collected and weighed. This solution was then diluted with water (1:10) and the amount of dissolved halide determined volumetrically by Fajan's titration using dichlorofluorescein as indicator.
Equilibrium between solid and solution phases was considered to be attained when analysis of the solution, made at progressive periods of time, gave the same value for dissolved halide.

**SOURCE AND PURITY OF MATERIALS:**
Magnesium chloride, reagent grade, was dried under vacuum before use.
Reagent grade N,N-dimethylformamide (C. Erba RP) was purified by fractional distillation under reduced pressure (2 mm Hg). The final product had a specific conductance of 3 × 10⁻⁵ S m⁻¹.

</table>

It has not been possible for the evaluator to obtain a copy of the original paper of Menshutkin (2). However, his data have been listed in a reference book translated by Stephen and Stephen (3). Since the original reference is not available, the original results of Menshutkin are not evaluated nor compiled and here are reported (for sake of comparison) only the values at 343, 353 and 363 K as obtained from Stephen and Stephen's book. They are:

<table>

</tr>
</tbody>
</table>

The agreement with the data of Sarkisov et al (1) is quite good. Nevertheless, the procedure used by Sarkisov et al. to determine solubility does not appear very accurate and no information is available for that adopted by Menshutkin. Therefore no values of solubility of sodium iodide in acetamide are recommended.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
Saturated solutions were prepared by dissolving the salt in acetamide in a vessel kept in a thermostatted oil bath. Samples of the solution were withdrawn with a pipet and transferred to a crucible. After evaporation of the solvent the residue was weighed and the concentration determined.

SOURCE AND PURITY OF MATERIALS:
Anhydrous and chemically pure potassium iodide was used. Acetamide was synthesised from acetic anhydride dissolved in ether and saturated with ammonia. Upon evaporation of the solvent, white crystals of acetamide precipitated. The product was then recrystallised twice from benzene. Acetamide so purified had a melting point of 82°C, a value slightly higher than that reported by Wallace (1)

ESTIMATED ERROR:
Solubility ± 5% (compiler)

REFERENCES:
Very few data on the solubility of halides in acetamide are available in the literature. In particular, the potassium chloride-acetamide system has been examined only by Wallace (1).

The results appear very reliable since this author has carefully purified the salt (by crystallization and fusion) and the solvent (by crystallization) and controlled the temperature.

Nevertheless, because of the lack of data from other sources which may serve as terms of comparison and evaluation, the results of Wallace (1) may only be reported as tentative values of the solubility.

EVALUATOR:
Bruno Scrosati
Istituto di Chimica Fisica
University of Rome, Italy
March, 1979

CRITICAL EVALUATION:
The potassium iodide-acetamide system has been investigated by Wallace (1), by Sarkisov et al. (2) and by Menshutkin (3).

Wallace has determined volumetrically the solubility at five temperatures i.e. 353, 358, 370, 391 and 403 K and the results seem reliable since the author has carefully purified the salt (by crystallization and fusion) and the solvent (by crystallization) and controlled the temperature of operation.

Sarkisov et al (2) have reported an analytical study of the sodium iodide-potassium iodide-acetamide system, in the course of which the concentrations of saturated NaI solutions in acetamide were determined gravimetrically at 343, 353 and 363 K.

The procedure for determining the solubility, however, does not appear very accurate and the data may be affected by an error which is estimated by the evaluator to be around 5%.

Considering this error, the values reported by Sarkisov et al (2) are in fair agreement with those obtained by Wallace (1).

It has not been possible for the evaluator to obtain a copy of the original paper by Menshutkin (3). However, his data have been listed in a reference book translated by Stephen and Stephen (4). Since the original reference is not available, the original results of Menshutkin (3) are not evaluated nor compiled and here are reported only the values at a few temperatures (as obtained from Stephen and Stephen's book) to compare them with those obtained by the other authors.

EVALUATOR:
Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
March 1979.

CRITICAL EVALUATION:
As far as the evaluator knows the lithium chloride-N-methylacetamide system has been investigated only by Dawson, Berger, Vaughn and Eckstrom (1).

These authors allowed long equilibration times to ensure saturation and carefully controlled the conditions of operation. The concentration of LiCl was then calculated from conductivity measurements as 17.51 g dm⁻³ of saturated solution at 313 K.

Even if the conductometric technique might be rigorously applied only to dilute solutions, this value appears acceptable as reliable indication of the solubility of LiCl in N-methylacetamide.

Tentative value of solubility of LiCl at 313 K

17.51 g dm⁻³ of saturated solution

Since the density of the saturated solution is not known, it is not possible to convert the data to molality units.

Solubility of lithium chloride at 40°C.

\[ 0.413 \text{ mol dm}^{-3} \]

**PREPARED BY:**
Bruno Scrosati

**AUXILIARY INFORMATION**

**METHOD/APPARATUS/PROCEDURE:**
The solubility was determined by preparing solutions containing 25 cm³ of solvent and excess of solute in glass stoppered flasks. These were placed in an oven at 40°C for one week and shaken frequently during this time. The flasks were then transferred to a thermostatted bath and held there for an additional week with frequent shaking to ensure saturation. To determine the concentration of the solute, a weighted amount of the solution was withdrawn and transferred to a tared conductance cell containing a known amount of solvent. The cell was weighed again and placed in a thermostatted bath where it was held for 12-24 hours with frequent shaking.

The conductance of this solution was then determined by standard procedure using a 1000 Hz impedance bridge (1).

The concentration of the solution was calculated from conductivity measurements using the following equation

\[ c = \frac{1000 L}{a - b\sqrt{c}} \] (continued)

**SOURCE AND PURITY OF MATERIALS:**
Reagent grade lithium chloride was dried in a vacuum desicator over anhydrous magnesium perchlorate and used without further treatment. N-methylacetamide was prepared by reacting monomethylamine with glacial acetic acid and subsequent heating to distil off water. The product was purified by fractional distillation followed by five or more fractional freezing cycles, using a procedure described in detail by Berger and Dawson (3).

**ESTIMATED ERROR:**
Solubility ± 0.05% (compiler)

**METHOD/APPARATUS/PROCEDURE:** (Continuation)

where \( c \) is the concentration of the solution, \( L \) the experimentally measured specific conductance and \( a \) and \( b \) the intercept and the slope, respectively, of a Kohlraush plot, determined in the same laboratory, for solutions at various LiCl concentration (2).

**SOURCE AND PURITY OF MATERIALS:** (Continuation)

The specific conductance of N-methylacetamide so purified ranged from \( 0.6 \times 10^{-5} \ \text{S} \ \text{m}^{-1} \) to \( 2 \times 10^{-5} \ \text{S} \ \text{m}^{-1} \) at 40°C.
CRITICAL EVALUATION:

Two investigations of the solubility of NaCl in N-methylacetamide have been reported (1-2).

Dawson et al. (1) allowed long equilibration times to ensure saturation and carefully controlled the conditions of operation. The concentration of NaCl was then calculated from Kohlrausch plots of solutions of the same salt.

Even if the conductometric technique might be rigorously applied only to dilute solutions, the value obtained by Dawson et al. (1) appears as a valuable indication of the solubility of NaCl in N-methylacetamide.

Chandra and Gopal (2) have determined the solubility of NaCl in N-methylacetamide at five temperatures, i.e. 305 K, 308 K, 313 K, 318 K and 323 K, respectively. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment). The solubility of NaCl was obtained gravimetrically by determining the anion content in the saturated solutions.

The method and the procedure seem to assure good reliability to the data of Chandra and Gopal (2), as also remarked by Lemire and Sears (3) in a recent review on the general properties of N-methylacetamide as solvent.

Finally, it has to be pointed out that Bonner, Jordon and Bunzl (4), in a paper dealing with the freezing point of electrolyte solutions in N-methylacetamide, briefly mentioned that alkali halides (and therefore possibly also sodium chloride, even if not specifically reported) are virtually insoluble in this solvent, without, however, giving experimental evidences to support this statement.

This observation largely contrasts with the experimental results of Dawson et al. (1) and of Chandra and Gopal (2) who have both found consistent solubility values of NaCl in particular and of alkali halides in general, in N-methylacetamide. However, as remarked by Gopal and Bhatnagar (5), electrolytes are generally extremely slow to dissolve in N-methylacetamide. Therefore, too short equilibration times may lead to underestimation of the solubility, as probably was the case of Bonner et al. (4).

Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Dawson et al. (1) with the molal solubility of Chandra and Gopal (2). However, considering that the time allowed by the latter authors for the equilibration of the solutions, i.e. 5 or 6 hours, may be too short to ensure complete saturation, the value of Dawson et al. (1), obtained after an equilibration time exceeding two weeks, is preferable as a tentative indication of the solubility.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
The solubility was determined gravimetrically. The procedure was described in detail in a previous paper from the same laboratory (1). Finely divided solute was added to a suitable quantity of N-methylacetamide contained in a flask. The flask was shaken continuously and then placed in a thermostat where the temperature was controlled within ± 0.05 °C in the lower range (35-40°C) and within ± 0.1 °C in the upper range (45-50°C). After stirring the solvent and the solute in the flask for 5 or 6 hours, the solute was allowed to settle. Three samples of the clear saturated solution were withdrawn at successive intervals with a pipette and weighted. The samples were then diluted with water and the anion content in the solution determined gravimetrically.

SOURCE AND PURITY OF MATERIALS:
Sodium chloride was purified by repeated crystallizations.
N-methylacetamide was dried over freshly ignited quicklime and then distilled under reduced pressure. The middle fraction was collected, fractionally crystallized twice and then distilled again under reduced pressure. The specific conductance of N-methylacetamide so purified was about 10⁻⁴ S m⁻¹.

ESTIMATED ERROR:

Solubility of sodium chloride at 40°C

0.339 mol dm⁻³

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
The solubility was determined conductometrically.
The method and the procedure for preparing the saturated solutions and determining their concentration are the same described in the course of the compilation of the lithium chloride-N-methylacetamide system, originally measured by Dawson, Berger, Vaughn and Eckstrom, to which we refer the reader for details.

SOURCE AND PURITY OF MATERIALS:
Reagent grade NaCl was dried in a vacuum desiccator over anhydrous magnesium perchlorate and used without further treatment. The preparation and the purification of N-methylacetamide have been described in the compilation of the lithium chloride-N-methylacetamide system, originally measured by Dawson, Berger, Vaughn and Eckstrom, to which we refer the reader for details.

ESTIMATED ERROR:
Solubility ± 0.5% (compiler).

REFERENCES:
Two investigations of the solubility of NaBr in N-methylacetamide have been reported (1–2).

Dawson et al. (1) have determined an approximate value of solubility at 313 K by incremental addition of small amounts of NaBr to a known volume of N-methylacetamide until saturation was visually observed. The solution was then heated to 333 K and it was assumed to have reached saturation if solute precipitated upon cooling to 313 K. This procedure is certainly open to some criticism and indeed the authors themselves attribute an error of ± 5% to their 'approximate' data (1).

Chandra and Gopal (2) have determined gravimetrically the solubility of NaBr in N-methylacetamide at five temperatures, i.e. 305 K, 308 K, 313 K, 318 K and 323 K, respectively. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment).

Even if the result of Chandra and Gopal (2) may be affected by a too short equilibration time, it still appears more reliable than the approximate value of Dawson et al. (1) for a tentative indication of the solubility.

EXPERIMENTAL VALUES:

Solubility of sodium bromide at 40°C

1.85 mol dm⁻³

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
An 'approximate'(authors) solubility value was determined by the use of a large test tube, fitted with a stopper and covered with aluminium foil, into which was placed 10 cm³ of solvent. The solute was added in small increments with constant shaking.

When the solution appeared to be saturated, the test tube was heated to 60°C in a water bath with frequent shaking. It was assumed that the solution had indeed reached saturation if solute precipitated upon cooling to 40°C.

The approximate solubility value, which the authors consider to have a precision of 5%, was determined on the basis of the salt added.

SOURCE AND PURITY OF MATERIALS:
Reagent grade sodium bromide was dried in a vacuum desiccator over anhydrous magnesium perchlorate and used without further treatment. As described in another paper from the same laboratory (1), N-methylacetamide was prepared by a reaction of monomethylamine with glacial acetic acid and subsequent heating to crack out and distil off water. The product was purified by fractional distillation followed by five or more

(2) N-methylacetamide; C₃H₇NO; 79-16-3

EVALUATOR:
Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
March 1979

CRITICAL EVALUATION:
The system sodium iodide-N-methylacetamide has been investigated by Dawson, Berger, Vaughn and Eckstrom (1) and by Chandra and Gopal (2).

Dawson et.al. (1) have reported an approximate value of solubility at 313 K determined by addition of small increments of NaI to a known volume of N-methylacetamide until saturation was visually observed. The solution was then heated to 333 K and it was assumed to have reached saturation if solute precipitated upon cooling to 313 K. This procedure is certainly open to some criticism and indeed the authors themselves attribute an error of ?5% to their 'approximate' data (1).

Chandra and Gopal (2) have determined gravimetrically the solubility of NaI in N-methylacetamide at five temperatures, i.e. 305 K, 308 K, 313 K, 318 K and 323 K, respectively. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment).

Even if the result of Chandra and Gopal (2) may be affected by a too short equilibration time, it still appears more reliable than the approximate value of Dawson et.al. (1) for a tentative indication of the solubility.

Tentative value of solubility of NaI at 313 K
562.7 g/kg of solvent.

Solubility of NaI as a function of temperature
For temperatures different than 313 K, only the data of Chandra and Gopal (2) are available, and these are

ESTIMATED ERROR:
Solubility ± 5% (authors)

REFERENCES:
Very few solubility data of pseudohalides in amides are available from the literature. In particular, so far as the evaluator knows, the system sodium thiocyanate-\(N\)-methylacetamide has been investigated only by Dawson, Berger, Vaughn and Eckstrom (1). These authors have reported an approximate value of the solubility (295.09 g dm\(^{-3}\) of saturated solution at 313 K), determined by addition of small increments of NaSCN to a known volume of \(N\)-methylacetamide until saturation was visually observed. The solution was then heated to 333 K and it was assumed to have reached saturation if solute precipitated upon cooling to 313 K. This procedure is open to some criticism and indeed the authors themselves attribute an error of \(\pm 5\%\) to their datum.

Therefore only an approximate value of the solubility of sodium thiocyanate in \(N\)-methylacetamide may be reported.

**Approximate value of solubility of NaSCN at 313 K**

\[
295.1 \text{ g dm}^{-3} \text{ of saturated solution}
\]

Since the density of the saturated solution is not known it is not possible to convert this datum into molal units.

Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
March 1979

CRITICAL EVALUATION:
The system potassium chloride-N-methylacetamide has been investigated by Dawson, Berger, Vaughn and Eckstrom (1) and by Chandra and Gopal (2).

Dawson et.al. (1) have determined the solubility of KCl in N-methylacetamide at 313 K by measuring the conductivity of the saturated solution. The concentration of the latter was obtained from Kohlrausch plots of solutions of the same salt. It has to be remarked that these authors allowed long equilibration times (over two weeks) to ensure saturation, and carefully controlled the conditions of operation. Chandra and Gopal (2) have determined gravimetrically the solubility of KCl in N-methylacetamide at five temperatures, i.e., 305 K, 308 K, 313 K, 318 K and 323 K. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment).

Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Dawson et.al. (1) with the molal solubility of Chandra and Gopal (2). However, considering that the time allowed by the latter authors for the equilibration of the solutions, i.e. 5 or 6 hours, may result too short to ensure complete saturation, the value of Dawson et.al. (1), obtained after equilibration times exceeding two weeks, becomes preferable as a tentative indication of the solubility.

Tentative value of solubility of KCl at 313 K
8.95 g dm$^{-3}$ of saturated solution.

Solubility of KCl as a function of temperature
For temperatures different than 313 K, only the data of Chandra and Gopal (2) are available and these are

Istituto di Chimica Fisica,
University of Rome, Italy.
March 1979

CRITICAL EVALUATION:

The system potassium bromide-N-methylacetamide has been investigated by Dawson, Berger, Vaughn and Eckstrom (1) and by Chandra and Gopal (2).

Dawson et.al. (1) have determined the solubility of KBr in N-methylacetamide by measuring the conductivity of the saturated solution. The concentration of the latter was obtained from Kohlrausch plots of solutions of the same salt. It has to be remarked that these authors allowed long equilibration times (over two weeks) to ensure saturation and carefully controlled the conditions of operation.

Chandra and Gopal (2) have determined gravimetrically the solubility of KBr in N-methylacetamide at five temperatures, i.e. 305 K, 308 K, 313 K, 318 K and 323 K. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment). However, the time allowed for equilibration of the solutions, i.e. 5 or 6 hours, may be in certain cases too short to ensure complete saturation. Indeed, as remarked by the same Gopal in a paper with Bhatnagar (3), electrolytes are generally extremely slow to dissolve in N-methylacetamide.

Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Dawson et.al. (1) with the molal solubility of Chandra and Gopal (2).

The possibility that the data of Chandra and Gopal (2) may be affected by a certain degree of error due to the short equilibration time has to be considered and the data of Dawson et.al. (1), obtained after equilibration times exceeding two weeks, became preferable in comparison for a tentative indication of the solubility of KBr in N-methylacetamide at 313 K.

Tentative value of solubility of KBr at 313 K

51.06 g dm⁻³ of saturated solution.

### REFERENCES:
Very few solubility data of pseudohalides in amides are available from the literature. In particular, the potassium thiocyanate-N-methylacetamide system has been investigated only by Dawson, Berger, Vaughn and Eckstrom (1).

These authors reported a solubility value at 313 K of 210.88 g dm\(^{-3}\) of saturated solution. The solubility was determined by measuring the conductivity of the saturated solution. The concentration of the latter was obtained from Kohlrausch plots of solutions of the same salt. It has to be remarked that precautions were taken to ensure saturation and to achieve precision in the measurements.

Nevertheless, because of the lack of data from other sources which may serve as terms of comparison and evaluation, the result of Dawson et al. is reported as tentative value of the solubility of potassium thiocyanate in N-methylacetamide.

**Tentative value of solubility of KSCN at 313 K**

\[
210.88 \text{ g dm}^{-3} \text{ of saturated solution}
\]

Since the density of the saturated solution is not known, it is not possible to convert this datum into molal units.

Solubility of potassium thiocyanate at 40°C

\[
2.17 \text{ mol dm}^{-3}
\]

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:
The solubility was determined conductometrically.
The method and the procedure for preparing the saturated solutions and determining their concentration are the same as described in the course of the compilation of the lithium chloride-N-methylacetamide system, originally measured by Dawson, Berger, Vaughn and Eckstrom, to which we refer the reader for details.

SOURCE AND PURITY OF MATERIALS:
Reagent grade KSCN was dried in a vacuum desiccator over anhydrous magnesium perchlorate and used without further treatment.
The preparation and purification of N-methylacetamide have been described in the compilation of the lithium chloride-N-methylacetamide system originally measured by Dawson, Berger, Vaughn and Eckstrom, to which we refer the reader for details.

ESTIMATED ERROR:
Solubility \(\pm 0.5\%\) (compiler)

REFERENCES:
N-Methylacetamide

COMPONENTS:
(1) Ammonium chloride; \( \text{NH}_4\text{Cl} \); 12125-02-9
(2) N-methylacetamide; \( \text{C}_3\text{H}_7\text{NO} \); 79-16-3

EVALUATOR:
Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
March 1979

CRITICAL EVALUATION:
The system ammonium chloride-N-methylacetamide has been investigated by Dawson, Berger, Vaughan and Eckstrom (1) and by Chandra and Gopal (2).

Dawson et al. (1) have determined the solubility of \( \text{NH}_4\text{Cl} \) in N-methylacetamide at 313 K by measuring the conductivity of the saturated solution. The concentration of the latter was obtained from Kohlrausch plots of solutions of the same salt.

It has to be remarked that these authors allowed long equilibration times (over two weeks) to ensure saturation and carefully controlled the conditions of operation.

Chandra and Gopal (2) have determined gravimetrically the solubility of \( \text{NH}_4\text{Cl} \) in N-methylacetamide at five temperatures, i.e., 305 K, 308 K, 313 K, 318 K and 323 K. These authors have used precautions both in assuring high purity of the salt (by repeated crystallizations) and in reducing contamination of the solvent and the solutions by moisture (by performing all the manipulations in a dry environment).

However, the time allowed for equilibration of the solutions, i.e., 5 or 6 hours, may be in certain cases too short to ensure complete saturation. Indeed, as remarked by the same Gopal in a paper with Bhatnagar (3), electrolytes are generally extremely slow to dissolve in N-methylacetamide.

Since the density of the saturated solution is not known, it is not possible to make a direct comparison of the molar solubility given by Dawson et al. (1) with the molal solubility of Chandra and Gopal (2).

The possibility that the data of Chandra and Gopal (2) may be affected by a certain degree of error due to the short equilibration time has to be considered and the data of Dawson et al. (1), obtained after equilibration times exceeding two weeks, become preferable in comparison for a tentative indication of the solubility of \( \text{NH}_4\text{Cl} \) in N-methylacetamide of 313 K.

Tentative value of solubility of \( \text{NH}_4\text{Cl} \) at 313 K

47.93 g dm\(^{-3}\) of saturated solution

Solubility of \( \text{NH}_4\text{Cl} \) as a function of temperature

For temperatures other than 313 K, only the data of Chandra and Gopal (2) are available and these are

March 1979

CRITICAL EVALUATION:
Very few solubility data for halides in amides are available in the literature. In particular, the potassium iodide-N-methylacetamide system has been investigated only by Dawson, Berger, Vaughn and Eckstrom (1).

These authors reported a solubility value at 313 K of 358.00 g dm$^{-3}$ of saturated solution. The solubility was determined by measuring the conductivity of the saturated solution. The concentration of the latter was obtained from Kohlrausch plots of solutions of the same salt. It has to be remarked that precautions were taken to ensure saturation and to achieve precision in the measurements.

Nevertheless, because of the lack of data from other sources which may serve as terms of comparison and evaluation, the result of Dawson et al. is reported as a tentative value of the solubility.

Tentative value of solubility of NH$_4$I at 313 K
358.00 g dm$^{-3}$ of saturated solution.

Since the density of the saturated solution is not known, it is not possible to convert this datum into molal units.

                                        University of Rome, Italy.

CRITICAL EVALUATION:

So far as the evaluator knows, the strontium chloride-N-methylacetamide system has been
investigated only by Chandra and Gopal(1).

These authors have determined gravimetrically the solubility of strontium chloride at
five temperatures using precautions both in assuring high purity of the salt (by
repeated crystallizations and heating to a constant weigh) and in reducing contamination
of the solvent and the solutions by moisture (by performing all the manipulations in a
dry environment).

However, the time allowed for equilibration of the solutions, i.e. 5 or 6 hours, may be in
certain cases too short to ensure complete saturation. Indeed, as remarked by the same
Gopal in a paper with Bhatnagar (2), electrolytes are generally extremely slow to dissolve
in N-methylacetamide. Therefore, the possibility that the data of Chandra and Gopal (1)
may be affected by a certain error has to be considered.

University of Rome, Italy.

March 1979

CRITICAL EVALUATION:
The system strontium bromide-N-methylacetamide has been investigated by Dawson, Berger, Vaughn and Eckstrom (1) and by Chandra and Gopal (2).

Dawson et al (1) have reported an approximate value of solubility at 313K determined by addition of small increments of \( \text{SrBr}_2 \) to a known volume of N-methylacetamide until saturation was visually observed. The solution was then heated to 333K and it was assumed to have reached saturation if solute precipitated upon cooling to 313K. This procedure is certainly open to some criticism and indeed the authors themselves attribute an error of \( \pm 5\% \) to their approximate data.

Chandra and Gopal (2) have determined gravimetrically the solubility of \( \text{SrBr}_2 \) in N-methylacetamide at five temperatures, i.e. 305K, 308K, 313K, 318K and 323K. These authors have used precautions both in assuring high purity and dryness of the salt (by repeated crystallizations and heating to a constant weigh) and in reducing contamination by moisture of the solvent and the solutions (by performing all the manipulations in a dry environment).

Even if the result of Chandra and Gopal (2) may be affected by a too short equilibration time, it still appears more reliable than the approximate value of Dawson et al (1) for a tentative indication of the solubility.

**Tentative value of solubility of \( \text{SrBr}_2 \) at 313K**

\[ 430.0 \text{ g/kg of solvent} \]

**Solubility of \( \text{SrBr}_2 \) as a function of temperature.**

For temperatures different than 313K, only the data of Chandra and Gopal (2) are available and these are

## AUXILIARY INFORMATION

### SOURCE AND PURITY OF MATERIALS:

Reagent grade SrBr₂ was dried in a vacuum desiccator over anhydrous magnesium perchlorate and used without further treatment.

The preparation and the purification of N-methylacetamide have been described in the compilation of the lithium chloride-N-methylacetamide system, originally measured by Dawson, Berger, Vaughn and Eckstrom, to which we refer the reader for details.

### ESTIMATED ERROR:

Solubility ± 5% (authors)

### REFERENCES:
COMPONENTS:
(1) Barium chloride; BaCl₂; 10361-37-2
(2) N-methylacetamide; C₃H₇NO; 79-16-3

CRITICAL EVALUATION:

So far as the evaluator knows the barium chloride-N-methylacetamide system has been investigated only by Chandra and Gopal (1).

These authors have determined gravimetrically the solubility of barium chloride at five temperatures using precautions both in assuring high purity and dryness of the salt (by repeated crystallizations and heating to a constant weight) and in reducing contamination by moisture of the solvent and the solutions (by performing all the manipulations in a dry environment).

However, the time allowed for equilibration of the solutions, i.e. 5 or 6 hours, may be in certain cases too short to ensure complete saturation. Indeed, as remarked by the same Gopal in a paper with Bhatnagar (2), electrolytes are generally extremely slow to dissolve in N-methylacetamide. Therefore, the possibility that the data of Chandra and Gopal (1) may be affected by a certain error has to be considered.

METHOD/APPARATUS/PROCEDURE:
The solubility was determined gravimetrically. The method and the procedure have been described in the course of the compilation of the sodium chloride-N-methylacetamide system, originally measured by Chandra and Gopal, to which we refer the reader for details.

SOURCE AND PURITY OF MATERIALS:
Barium bromide was purified by repeated crystallizations. The salt was then heated to a constant weight to make it anhydrous. The purification of N-methylacetamide has been described in the course of the compilation of the sodium chloride-N-methylacetamide system, originally measured by Chandra and Gopal, to which we refer the reader for details.

ESTIMATED ERROR:
Solubility ± 0.5% (authors)
Temperature ± (0.05-0.1)°C (authors)

REFERENCES:
COMPONENTS:
(1) Lithium chloride; LiCl; 7447-41-8
(2) N, N-dimethylacetamide; C₄H₉NO; 127-19-5

EVALUATOR:
Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
May 1979.

CRITICAL EVALUATION:
The lithium chloride-N, N-dimethylacetamide system has been examined by Pistoia and Scrosati (1), by Lesteva and Chernaya (2) and by Federov et. al. (3).

The result of the latter authors (2.00 mol dm⁻³ at 295-298 K) is rejected since no purification of the solute and the solvent was described and no control of the temperature was attempted.

The solubility determined by Pistoia and Scrosati (1) at 298 K (86.0 g/kg of solvent) appears to be a more accurate value since these authors have taken precautions to prepare pure solute and solvent, to operate in dry conditions and to control the temperature.

Lesteva and Chernaya (3) have examined the ternary lithium chloride-dimethylacetamide-water system and found that several compounds are present in equilibrium with the liquid phase. Four compounds of lithium chloride with dimethylacetamide (DMA) were detected in the system, with the following compositions, 4LiCl.DMA, 1.5LiCl.DMA, LiCl.DMA and LiCl.2DMA, respectively.

When describing their solubility studies, Lesteva and Chernaya (3) neither reported the source and the purity of the materials nor the purification of the solvent. However, the procedure to obtain the solubility values appears accurate both in controlling the temperature of operation and in determining the LiCl concentration in the saturated solutions.

The authors (3) have reported values of solubility of LiCl in N, N-dimethylacetamide at three temperatures, i.e. 293K, 313K and 333K respectively, with the results reported in the following table.

<table>
<thead>
<tr>
<th>T/K</th>
<th>mol/kg</th>
</tr>
</thead>
<tbody>
<tr>
<td>293</td>
<td>2.03</td>
</tr>
<tr>
<td>313</td>
<td>2.52</td>
</tr>
<tr>
<td>333</td>
<td>2.92</td>
</tr>
</tbody>
</table>

The solubility data may be represented as function of temperature by the equation

\[ \log c \text{ (mol/kg)} = -\frac{386.522}{(T/K)} + 1.629 \]

The calculated value at 298 K, i.e. 91.1 g/kg of solvent, is in fair agreement with that reported by Pistoia and Scrosati (1). As recommended value is then taken the average between the datum of Pistoia and Scrosati (1) and that of Lesteva and Chernaya (3).

Recommended value of solubility of LiCl at 298 K.

**PREPARED BY:**

Bruno Scrosati

**METHOD/APPARATUS/PROCEDURE:**

The solubility value was determined by mixing the halide with the solvent in a vessel maintained at constant temperature. The solution was stirred until equilibrium was established in the system. The amount of time allowed for reaching this condition is not reported by the authors. Specimen of the liquid phase were analysed for lithium chloride argentometrically. The composition of the solid phase was determined from the Schreinemakers rays (1).

**SOURCE AND PURITY OF MATERIALS:**

Not reported.

**ESTIMATED ERROR:**

Solubility ± 0.2-0.5%
Temperature ± 0.05 K (authors)

**REFERENCES:**

(1) Schreinemakers, F.A.H., J. Phys. Chem. 1906, 58, 73-75
**COMPONENTS:**

1. Lithium chloride; LiCl; 7447-41-8
2. N,N-dimethylacetamide; C₄H₉NO; 127-19-5

**ORIGINAL MEASUREMENTS:**

- Pistoia, G.; Scrosati, B.

**VARIABLES:**

One temperature: 25°C

**PREPARED BY:**

Bruno Scrosati

**EXPERIMENTAL VALUES:**

Solubility of lithium chloride at 25°C

8.60 g/100g of solvent

**METHOD/APPARATUS/PROCEDURE:**

The method and the apparatus for the solubility measurements were those described in a previous paper from the same laboratory (1). The solubility value was determined by dissolving the halide in about 20-25 cm³ of solvent contained in a 50 cm³ pyrex flask with a standard taper joint. The addition of the salt was continued until apparent saturation was reached. The solution was then stirred at room temperature for several hours and finally left for three or more days in a stirred thermostatic bath. An aliquot of the saturated solution was then collected with the aid of a siphon provided with a terminal G-3 gooch. This solution was diluted with water in the 1/10 ratio and the amount of the dissolved salt was determined by volumetric Mohr titration. The reliability of the method was checked by dissolving known amounts of the salt and then titrating the resulting solution with the procedure above described. 0.1400 g of LiCl were added and 0.1395g found, thus showing an accuracy of 0.4% (authors).

**SOURCE AND PURITY OF MATERIALS:**

- Lithium chloride, reagent grade commercial product, was dried under vacuum.
- Reagent grade dimethylacetamide was purified by fractional distillation under reduced pressure (2mm Hg).
- The final product had a specific conductance of 2.10⁻⁵ S m⁻¹, in good agreement with the value reported by Lester, Gover and Sears (2), i.e. (0.8-2), 10⁻⁵ S m⁻¹.
- To avoid contamination with the atmosphere the solution was prepared in a dry-box.

**ESTIMATED ERROR:**

- Solubility ± 0.4%
- Temperature ± 0.05°C (authors)

**REFERENCES:**

1. Pistoia, G.; Pecci, G.; Scrosati, B.
  *Rio.Sci.*, 1967, 37, 1167-1172
2. Lester, G.; Gover, T.; Sears, P.
CRITICAL EVALUATION:
The system lithium bromide-\(N, N\)-dimethylacetamide has been examined by Pistoia and Scrosati (1) and by Federov et al. (2).

The result of the latter authors (2.60 mol dm\(^{-3}\)) is rejected since no purification of the solute and the solvent was described and the temperature (reported as 295-298 K) was not controlled.

The solubility determined by Pistoia and Scrosati (1) at 298 K (262 g/kg of solvent) appears to be more accurate since these authors have taken precautions to prepare pure solute and solvent, to operate in dry conditions and to control the temperature.

Nevertheless, because of the lack of reliable data from other sources which may serve as quantities of comparison and evaluation, the result of Pistoia and Scrosati (1) may only be reported as a tentative value.

Tentative value of solubility of LiBr at 298 K

\[

### EVALUATOR:

Bruno Scrosati,  
Istituto di Chimica Fisica,  
University of Rome, Italy.  
May 1979

### CRITICAL EVALUATION:

Very few solubility data of halides in acetamides are available from the literature. In particular, the system lithium iodide-N,N-di methylacetamide has been examined only by Fedorov et al. (1), who reported a solubility value of 0.95 mol/liter at 295-298 K.

In other systems, where more reliable data from other sources are available (see for instance the lithium chloride-N,N-dimethylacetamide one), the results of Fedorov et al. (1) are rejected since these are affected by lack of information on the purification of the solute and the solvent and by no control of the temperature.

However, in cases such as the present one, where the data of Fedorov et al. (1) are the only ones available, the results of these authors have been compiled and reported as very approximate values of solubility.

Approximate value of solubility of LiI at 298 K

\[
\text{43 g dm}^{-3}\text{ of saturated solution.}
\]

Since the density of the saturated solution is not known it is not possible to convert this datum into molal units.

Istituto di Chimica Fisica,
University of Rome, Italy.
May 1979

CRITICAL EVALUATION:
The sodium chloride-N,N-dimethylacetamide system has been investigated by Pistoia and Scrosati (1) and by Fedorov et.al. (2).

The latter authors stated that sodium chloride is 'not soluble' in N,N-dimethylacetamide. This statement is however rejected since no purification of the solvent was described and the temperature not controlled in the investigation of Fedorov et.al. (2).

The solubility determined by Pistoia and Scrosati (1) at 298 K (0.2 g/kg of solvent) appears to be more accurate since these authors have taken precautions to prepare pure solute and solvent, to operate in dry conditions and to control the temperature.

Nevertheless, because of the lack of reliable data from other sources which may serve as quantities of comparison and evaluation, the result of Pistoia and Scrosati (1) may only be reported as a tentative value of the solubility of sodium chloride in N,N-dimethylacetamide at 298 K.

COMPONENTS:
(1) Sodium thiocyanate; NaSCN; 540-72-7
(2) N,N-dimethylacetamide; C₄H₉NO; 127-19-5

EVALUATOR:
Bruno Scrosati,
Istituto di Chimica Fisica,
University of Rome, Italy.
May 1979.

CRITICAL EVALUATION:
Very few solubility data of pseudohalides in acetamides are available in the literature. In particular the sodium thiocyanate-N,N-dimethylacetamide system has been investigated only by Fedorov et.al. (1), who reported a value of 1.78 mol dm⁻³ at 295±298 K.

In other systems, where more reliable data from other sources are available, the results of Fedorov et.al. (1) are rejected since no purification of the solvent nor control of temperature was attempted by these authors in their investigation.

However, in the cases like the present one, where the data of Fedorov et.al. (1) are the only available, the results of these authors have been compiled and reported as very approximate values of solubility.

Approximate value of solubility of NaSCN at 298 K

144 g dm⁻³ of saturated solution.

Since the density of the saturated solution is not known it is not possible to convert this datum into molal units.

2. N,N-dimethylacetamide; C₄H₉NO; 127-19-5

### ORIGINAL MEASUREMENTS:

### VARIABLES:

One temperature: 22-25°C

### EXPERIMENTAL VALUES:

Solubility of sodium thiocyanate at 22-25°C

\[ 1.78 \text{ mol dm}^{-3} \]

### AUXILIARY INFORMATION

#### METHOD/APPARATUS/PROCEDURE:

The saturated solution was prepared at 'ambient' temperature (22-25°C) adding excess of solute to freshly distilled solvent. The solution was kept in a desiccator for three days. The amount of dissolved salt in the solution was the evaluated by titrating the thiocyanate ions with standard mercuric solution.

#### SOURCE AND PURITY OF MATERIALS:

Sodium thiocyanate was dried under vacuum. No details on the purification of N,N-dimethylacetamide are reported.

#### ESTIMATED ERROR:

Solubility ±10% (compiler)

Istituto di Chimica Fisica,
University of Rome, Italy.
May 1979.

CRITICAL EVALUATION:
The potassium chloride-N,N-dimethylacetamide system has been investigated by Pistoia and Scrosati (1) and by Fedorov et. al. (2).

The latter authors stated that potassium chloride is 'not soluble' in N,N-dimethylacetamide. This statement, however, is rejected since no purification of the solvent was described and no control of the temperature was attempted in the investigation of Fedorov et. al. (2).

The solubility determined by Pistoia and Scrosati (1) at 298 K (0.11 g/kg of solvent) appears to be more accurate since these authors have taken precautions to prepare pure solute and solvent, to operate in dry conditions and to control the temperature.

Nevertheless, because of the lack of reliable data from other sources which may serve as quantities of comparison and evaluation, the result of Pistoia and Scrosati (1) may only be reported as a tentative value of the solubility of potassium chloride in N,N-dimethylacetamide at 298 K.

**CRITICAL EVALUATION:**

The potassium bromide–N,N-dimethylacetamide system has been investigated by Pistoia and Scrosati (1) and by Fedorov et.al. (2).

Pistoia and Scrosati (1) reported a solubility at 298 K of 3.9 g/kg of solvent. This value appears reliable since the authors have taken precautions to prepare pure solute and solvent, to operate in dry conditions and to control the temperature.

The datum of Fedorov et.al. (2) at 295–298 K (0.03 mol dm⁻³) cannot be used as a reliable quantity of comparison and evaluation, since these authors have not attempted to purify the solvent nor to control the temperature.

The datum of Fedorov et.al. (2) is therefore rejected and the result of Pistoia and Scrosati (1) is reported as a tentative value of the solubility of potassium bromide in N,N-dimethylacetamide at 298 K.

### AUXILIARY INFORMATION

**METHOD/APPARATUS/PROCEDURE:**

The saturated solution was prepared at 'ambient' temperature (22-25°C) adding excess of solute to freshly distilled solvent. The solution was kept in a desiccator for three days. The amount of dissolved salt in the solution was then evaluated by titrating the chloride ion with standard mercuric solution.

**SOURCE AND PURITY OF MATERIALS:**

Strontium chloride was dried under vacuum. No details on the purification of N,N-dimethylacetamide are reported.

**ESTIMATED ERROR:**

Solubility ± 10% (compiler)

**REFERENCES:**
SYSTEM INDEX

Underlined page numbers refer to the evaluation text and those not underlined to the compiled tables for that system. The compounds are listed in the order as used in the Chemical Abstracts indexes, for example, N-methylformamide is listed as formamide,N-methyl- and sodium thiocyanate as thiocyanic acid, sodium salt.

A

Acetamide + potassium bromide + potassium chloride + potassium iodide + sodium iodide

Acetamide,N-methyl + ammonium bromide + ammonium chloride + ammonium iodide + barium bromide + barium chloride + calcium bromide + calcium chloride + lithium chloride + potassium bromide + potassium chloride + potassium iodide + sodium bromide + sodium chloride + sodium iodide + strontium bromide + strontium chloride + thiocyanic acid, ammonium salt + thiocyanic acid, potassium salt + thiocyanic acid, sodium salt

Acetamide,N,N-dimethyl + calcium bromide + calcium chloride + calcium iodide + lithium bromide + lithium chloride + lithium iodide + magnesium chloride + magnesium iodide + potassium bromide + potassium chloride + potassium iodide + sodium bromide + sodium chloride + sodium iodide + strontium chloride + thiocyanic acid, potassium salt + thiocyanic acid, sodium salt

Ammonium bromide + acetamide, N-methyl-

+ formamide

+ formamide, N-methyl-

+ formamide, N,N-dimethyl-

Ammonium chloride + acetamide, N-methyl-

+ formamide

+ formamide, N-methyl-

+ formamide, N,N-dimethyl-

Ammonium iodide + acetamide, N-methyl-

+ formamide

+ formamide, N-methyl-

+ formamide, N,N-dimethyl-

Ammonium thiocyanate, see thiocyanic acid, ammonium salt

B

Barium bromide + acetamide, N-methyl-

+ formamide

Barium chloride + acetamide, N-methyl-

+ formamide
