

<p>COMPONENTS:</p> <p>(1) Methane; CH₄; [74-82-8]</p> <p>(2) Water; H₂O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Rubin Battino Department of Chemistry Wright State University Dayton, OH 45435 USA</p> <p>1985, January</p>
<p>CRITICAL EVALUATION:</p> <p>AN EVALUATION OF THE SOLUBILITY OF METHANE IN WATER BETWEEN TEMPERATURES OF 273.15 and 523.15 K AT A METHANE PARTIAL PRESSURE OF 0.101325 MPa.</p> <p>Normally only one equation and table of smoothed data are given in an evaluation. This evaluation gives three equations and two tables of smoothed data. Equation (1) represents the best evaluation of data prior to 1981. Equation (2) and Table 1 represent the recommended evaluation between temperatures of 273.15 and 328.15 K based on the precise measurements of Rettich <i>et al.</i> (22). Equation (3) and Table 2 represent tentative values between temperatures of 273.15 and 523.15 K based on data from Rettich <i>et al.</i> (22) and Crovetto <i>et al.</i> (9). For applications around room temperature the data represented by Equation (2) and Table 1 are recommended.</p> <p>The solubility of methane in water is reported in many papers (1-33). Most of these measurements are at <i>ca.</i> atmospheric pressure, but there are many measurements reported at larger pressures which will be evaluated separately. Many of the papers contain additional data on the solubility of methane in aqueous electrolyte solutions and in mixed solvents.</p> <p>The thirty-three papers that were examined for the evaluation are listed alphabetically in the reference list. The recent results reported by Rettich <i>et al.</i> (22) are at least an order of magnitude more precise than the data reported in any other papers. Seven papers published prior to 1981 were judged to contain more reliable data (3, 4, 7, 20, 28, 31, 32) than the other papers. A linear regression of the 36 data points in the 274 to 313 K temperature interval from the seven papers gave the equation</p> $\ln x_1 = -78.1584 + 104.4791/\tau + 29.7802 \ln \tau \quad (1)$ <p>with a standard deviation of 0.0050 in $\ln x_1$ or about 0.50 percent in x_1 at the middle of the temperature range. The sixteen data points from Rettich <i>et al.</i> (22) give the equation for the 275 to 328 K temperature range of</p> $\ln x_1 = -115.647716 + 155.575631/\tau + 65.2552591 \ln \tau - 6.616975729 \tau \quad (2)$ <p>with a standard deviation in x_1 of 0.056 percent. In both equations $\tau = (T/100 \text{ K})$. In Equation (1) the mole fraction solubility, x_1, is for a partial pressure of 0.101325 MPa methane. In Equation (2) the mole fraction is for a fugacity of 0.101325 MPa methane. Rettich <i>et al.</i> (22) used a rigorous thermodynamic approach described in their paper to convert their</p>	

<p>COMPONENTS:</p> <p>(1) Methane; CH₄; [74-82-8]</p> <p>(2) Water; H₂O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Rubin Battino Department of Chemistry Wright State University Dayton, OH 45435 USA</p> <p>1985, January</p>
--	---

CRITICAL EVALUATION:

experimental measurements to mole fraction solubility values. The mole fraction solubilities calculated from Equation (2) are 1 - 2 percent larger at 273.15 K and 0.20 percent larger at 313 K. Both equations have been extrapolated to 373 K. At the larger temperatures Equation (2) gives smaller solubility values than Equation (1). At 373 K Equation (2) gives a solubility value that is eleven percent smaller than the value calculated from Equation (1). Table 1 contains the smoothed data calculated from Equation (2). Equation (2) and the data smoothed at 5 K intervals from 273.15 to 328.15 K are *recommended* values of the mole fraction solubility of methane in water at a fugacity of 0.101325 MPa. The extrapolated values between 333.15 and 373.15 K are tentative. Also given in Table 1 are ideal gas Ostwald coefficients and enthalpy, entropy and constant pressure heat capacity changes for the transfer of one mole of methane from the gas phase to the infinitely dilute solution in water. The mole fraction solubility at 0.101325 MPa fugacity methane shows a minimum at 363 K.

Recently Crovetto *et al.* (9) measured the solubility of methane in water from 297 to 518 K over a fugacity range of 1.3 to 6.5 MPa with an estimated precision in the Henry's constant of 1 - 2 percent. The evaluator computed mole fraction methane solubility values in water at a partial pressure of 0.101325 MPa assuming Henry's law is obeyed. The seven values from the work of Crovetto *et al.* (9) were combined with the 16 values of Rettich *et al.* (22) in a linear regression to yield the equation for the mole fraction solubility of methane at a partial pressure of 0.101325 MPa (1 atm) over the 273.15 to 523.15 temperature range of:

$$\ln x_1 = -99.14188 + 132.821/\tau + 51.91445 \ln \tau - 4.25831 \tau \quad (3)$$

where again $\tau = (T/100 \text{ K})$. The standard deviation in $\ln x_1$ is 0.015, and the percent error in x_1 at the middle of the temperature range is 1.5 percent. Smoothed tentative values of the mole fraction solubility and the thermodynamic changes on solution at 10 K intervals from 273.15 to 523.15 K are given in Table 2. Equation (3) and the smoothed data in Table 2 are for the use of workers who need values in the 373 to 523 K temperature range at a methane partial pressure of 0.101325 MPa. For values at larger partial pressures see the evaluation of high pressure methane in water solubility data.

AUXILIARY INFORMATION																																																					
METHOD/APPARATUS/PROCEDURE: <p>The original apparatus was described in references (1, 2). Degassed solvent flows in a thin film through the gas down an absorption helix. The gas absorbed and the solvent volume used are read on burets.</p> <p>NOTE: In the authors earlier paper (ref 2) they report five methane solubility values in water at 298.2 ± 0.1 K of 27.9, 27.8, 27.9, 27.8 and 27.9 cm³ dm⁻³ (gas volume at STP). The results are about 7 per cent smaller than the results reported in this paper. They are considered preliminary results and no data sheet was prepared for them.</p>	SOURCE AND PURITY OF MATERIALS: (1) Methane. Prepared by the authors from Grignard reagent. (2) Water. Distilled.

AUXILIARY INFORMATION																							
METHOD/Apparatus/Procedure: A 20 ml volume of degassed solvent (sublimation technique) is transferred to a previously evacuated (10^{-4} mmHg) saturation cell immersed in an insulated controlled (± 0.01 K) water bath. The gas is dispersed through the constantly stirred solution at 1 atm by a coarse, fritted glass disc. Saturation is obtained within a few hours. Prior to analysis the solution is allowed to sit under 1 atm gas pressure for one hour. A saturated sample is withdrawn from the saturation cell using a greaseless, gas tight (2.500 ± 0.001 ml) Gilmont syringe. A 0.250 ml sample is injected to "wet" the frit. It is stripped and then four 0.500 ml samples are injected sequentially into the cell. The stripped gas is dried before entering the column. The gas is analyzed on a dual filament conductivity detector. Calibrations with pure gas are made dry before and wet after each series of runs.	SOURCE AND PURITY OF MATERIALS: (1) Methane. No information. (2) Water. No information. ESTIMATED ERROR: $\delta x_1/x_1 = \pm 0.015$ (compiler) REFERENCES:

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
<p>The apparatus used was modelled after that of Benson, Krause, and Peterson (1). Degassed water is flowed in a thin film over the surface of a one dm³ sphere to contact the gas. After equilibrium is attained the solution is sealed in a chamber of calibrated volume. The dissolved gas is extracted and its amount determined by a direct PVT measurement. A sample of the gas phase is analyzed in an identical manner. From the results, the saturation pressure of the solvent and Henry's constant are calculated in a thermodynamically rigorous manner, applying all non-ideal corrections.</p> <p>The authors smoothing equation, which fits their data to 0.06 %, is:</p> $\ln H = 127.174 - 155.5756/(T/100 \text{ K})$ $- 65.2553 \ln (T/100 \text{ K})$ $+ 6.1698 (T/100 \text{ K}). \quad \text{For } H/\text{Pa}.$			<p>(1) Methane. Airco. Both chemical pure grade, 99.0 minimum mole percent, and ultrahigh purity grade, 99.99 minimum mole percent were used with no detectable difference in results.</p> <p>(2) Water. Reverse osmosis, "house-distilled" Resistivity greater than 5 x 10⁴ Ωm.</p>
