FOREWORD

If the knowledge is undigested or simply wrong, more is not better.

The Solubility Data Series is a project of Commission V.8 (Solubility Data) of the International Union of Pure and Applied Chemistry (IUPAC). The project had its origins in 1973, when the Analytical Chemistry Division of IUPAC set up a Subcommission on Solubility Data under the chairmanship of the late Prof. A.S. Kertes. When publication of the Solubility Data Series began in 1979, the Committee became a full commission of IUPAC, again under the chairmanship of Prof. Kertes, who also became Editor-in-Chief of the Series. The Series has as its goal the preparation of a comprehensive and critical compilation of data on solubilities in all physical systems, including gases, liquids and solids.

The motivation for the Series arose from the realization that, while solubility data are of importance in a wide range of fields in science and technology, the existing data had not been summarized in a form that was at the same time comprehensive and complete. Existing compilations of solubility data indeed existed, but they contained many errors, were in general uncritical, and were seriously out-of-date.

It was also realized that a new series of compilations of data gave educational opportunities, in that careful compilations of existing data could be used to demonstrate what constitutes data of high and lasting quality. As well, if the data were summarized in a sufficiently complete form, any individual could prepare his or her own evaluation, independently of the published evaluation. Thus, a special format was established for each volume, consisting of individual data sheets for each separate publication, and critical evaluations for each separate system, provided sufficient data from different sources were available for comparison. The compilations and, especially, the evaluations were to be prepared by active scientists who were either involved in producing new data, or were interested in using data of high quality. With minor modifications in format, this strategy has continued throughout the Series.

In the standard arrangement of each volume, the Critical Evaluation gives the following information:

- (i) A text which discusses the numerical solubility information which has been abstracted from the primary sources in the form of compilation sheets. The text concerns primarily the quality of the data, after consideration of the purity of the materials and their characterization, the experimental method used, the uncertainties in the experimental values, the reproducibility, the agreement with accepted test values, and, finally, the fitting of the data to suitable functions, along with statistical tests of the fitted data.
- (ii) A set of recommended data, whenever possible, including weighted averages and estimated standard deviations. If applicable, one or more smoothing equations which have been computed or verified by the evaluator are also given.
- (111) A graphical plot of the recommended data, in the form of phase diagrams where appropriate.

The Compilation part consists of data sheets which summarize the experimental data from the primary literature. Here much effort is put into obtaining complete coverage; many good data have appeared in publications from the late nineteenth and early twentieth centuries, or in obscure journals. Data of demonstrably low precision are not compiled, but are mentioned in the Critical Evaluation. Similarly, graphical data, given the uncertainty of accurate conversion to numerical values, are

compiled only where no better data are available. The documentation of data of low precision can serve to alert researchers to areas where more work is needed.

- A typical data sheet contains the following information:
 - (i) list of components: names, formulas, Chemical Abstracts Registry Numbers;
 - (ii) primary source of the data;
 - (iii) experimental variables;
 - (iv) compiler's name;
 - (v) experimental values as they appear in the primary source, in modern units with explanations if appropriate;
 - (vi) experimental methods used;
 - (vii) apparatus and procedure used;
- (viii) source and purity of materials used;
 - (ix) estimated error, either from the primary source or estimated by the compiler;
 - (x) references relevant to the generation of the data cited in the primary source.

Each volume also contains a general introduction to the particular type of system, such as solubility of gases, of solids in liquids, etc., which contains a discussion of the nomenclature used, the principles of accurate determination of solubilities, and related thermodynamic principles. This general introduction is followed by a specific introduction to the subject matter of the volume itself.

The Series embodies a new approach to the presentation of numerical data, and the details continue to be influenced strongly by the perceived needs of prospective users. The approach used will, it is hoped, encourage attention to the quality of new published work, as authors become more aware that their work will attain permanence only if it meets the standards set out in these volumes. If the Series succeeds in this respect, even partially, the Solubility Data Commission will have justified the labour expended by many scientists throughout the world in its production.

January, 1989

J.W. Lorimer, London, Canada

PREFACE

This volume in the Solubility Data Series contains tabulations, collections, and critical evaluations of original data for the solubility of carbon monoxide in a variety of liquid solvents. Most of the studies reported were made at temperatures around ambient, and for partial pressures of carbon monoxide around 101.3 kPa. Some data, however, are for temperatures as low as 93 K and as high as 573 K, and for pressures up to 101 MPa.

Within this volume, material is arranged according to solvent class, with solubility data for low pressures and high pressures collected together. To introduce each section a critical evaluation has been written, incorporating comments for each individual solvent in that class. In only a few cases, however, has there been a sufficient number of detailed studies to enable the evaluators to recommend a set of solubility values for carbon monoxide in a particular solvent.

Carbon monoxide is a toxic, flammable, colorless gas, formed when carbon or any carbon-based fuel burns with a deficiency of oxygen. Its discovery is attributed to Joseph Marie Francois de Lassone (1776), who obtained it by heating a mixture of charcoal and zinc oxide. Commercially, carbon monoxide is usually obtained from "producer-gas" (25% carbon monoxide) and "water-gas" (40% carbon monoxide), in a combined cycle blowing air and steam alternately through incandescent coke. In the laboratory, common preparation methods involve the dehydration of formic acid by concentrated sulfuric acid, or the reaction of concentrated sulfuric acid with oxalate or with hexacyanoferrate(II). Very pure carbon monoxide can be made by decomposing nickel tetracarbonyl at 200°C.

For over at least a century, carbon monoxide has had a variety of uses. It has been a fuel (a component of early "town-gas" or "coal-gas"), a reducing agent (large amounts utilised in metallurgy), and more recently a feedstock for the manufacture of many organic chemicals. This latter application is largely a result of research into the structure and properties of carbonyl complexes of transition metals. A recognition of the special π -bonding ability of carbon monoxide as a ligand for transition metals in low oxidation state opened up a large area of modern inorganic chemistry, and led to the production of the efficient catalytic systems already producing large tonnages of organic chemicals annually.

Emissions of carbon monoxide, principally from motor vehicle exhausts, are a primary source of air pollution. Efforts to monitor and reduce emissions of this pollutant are now being made worldwide because of its hazard to health. The toxicity of carbon monoxide is actually a consequence of its ability to form the π-bonds referred to above. For the normal physiological function of transporting oxygen, the dioxygen molecules are reversibly bonded to iron atoms in hemoglobin. The carbon monoxide - hemoglobin complex, however, is about 300 times more stable than the oxygen-hemoglobin complex. Thus inhalation of carbon monoxide leads to the formation of carboxy-hemoglobin in the blood, starving it, and the cells it supplies, of vital oxygen. Progressively headache, dizziness, nausea, unconsciousness, and eventual death may occur.

The solubility of carbon monoxide in biological fluids is a primary consideration in the toxicity process. Also the solubility of carbon monoxide in appropriate aqueous and non-aqueous solvents needs to be known in order to understand and improve methods of conversion of carbon monoxide into various organic chemicals, and methods of controlling carbon monoxide pollution. Such solubility data have been collected and evaluated in this volume.

Carbon monoxide melts at 68.09 K and boils at 81.65 K under 101.3 kPa pressure. It has a critical temperature, pressure, and density of 132.9 K, 3.496 MPa, and 301.0 kg m $^{-3}$ respectively. Its triple point is 68.1 K, 15.39 kPa; its autoignition temperature 925 K. The molar volume is 22.408 dm 3 at 273.15 K, 101.325 kPa, so that no correction for non-ideality of the gas needs to be made for the purposes of calculating solubility data from measurements made around ambient temperatures and pressures.

This volume contains data on the solubility of carbon monoxide taken from a search of the world's chemical literature through to the end of 1988. (The editor would be grateful to learn of any articles which were missed in the search). Its publication is timely in view of current concern about carbon monoxide as an atmospheric pollutant, and in view of the role which carbon monoxide is likely to play in the future, as chemical feedstocks may have to change in response to supply and demand patterns, and as alternative energy sources are developed, especially coal gasification technology. For all of these applications, and for numerous others, well documented and critically evaluated gas solubility data will be of tremendous benefit. As a historical survey, this volume also indicates where data are not available, and shows where original investigations are required. More work needs to be done to corroborate some of the published data, to extend their temperature and pressure ranges, and to investigate other solvents for such a common and important a gas as carbon monoxide.

The editor would like to express his gratitude to fellow members of the I.U.P.A.C. Commission on Solubility Data for their help and advice; to Dundee Institute of Technology for partly supporting travel connected with the project and for providing some of the library facilities required; and to Carolyn Dowie, Lesley Flanagan, and Ann Ramsay, who were involved in typing the final manuscript.

THE SOLUBILITY OF GASES IN LIQUIDS

R. Battino, H. L. Clever and C. L. Young

INTRODUCTION

The Solubility Data Project aims to make a comprehensive search of the literature for data on the solubility of gases, liquids and solids in liquids. Data of suitable accuracy are compiled into data sheets set out in a uniform format. The data for each system are evaluated and where data of sufficient accuracy are available values recommended and in some cases a smoothing equation suggested to represent the variation of solubility with pressure and/or temperature. A text giving an evaluation and recommended values and the compiled data sheets are published on consecutive pages.

DEFINITION OF GAS SOLUBILITY

The distinction between vapor-liquid equilibria and the solubility of gases in liquids is arbitrary. It is generally accepted that the equilibrium set up at 300K between a typical gas such as argon and a liquid such as water is gas liquid solubility whereas the equilibrium set up between hexane and cyclohexane at 350K is an example of vapor-liquid equilibrium. However, the distinction between gas-liquid solubility and vapor-liquid equilibrium is often not so clear. The equilibria set up between methane and propane above the critical temperature of methane and below the critical temperature of propane may be classed as vapor-liquid equilibrium or as gas-liquid solubility depending on the particular range of pressure considered and the particular worker concerned.

The difficulty partly stems from our inability to rigorously distinguish between a gas, a vapor, and a liquid, which has been discussed in numerous textbooks. We have taken a fairly liberal view in these volumes and have included systems which may be regarded, by some workers, as vapor-liquid equilibria.

UNITS AND QUANTITIES

The solubility of gases in liquids is of interest to a wide range of scientific and technological disciplines and not solely to chemistry. Therefore a variety of ways for reporting gas solubility have been used in the primary literature and inevitably sometimes, because of insufficient available information, it has been necessary to use several quantities in the compiled tables. Where possible, the gas solubility has been quoted as a mole fraction of the gaseous component in the liquid phase. The units of pressure used are bar, pascal, millimeters of mercury and atmosphere. Temperatures are reported in Kelvin.

EVALUATION AND COMPILATION

The solubility of comparatively few systems is known with sufficient accuracy to enable a set of recommended values to be presented. This is true both of the measurement near atmospheric pressure and at high pressures. Although a considerable number of systems have been studied by at least two workers, the range of pressures and/or temperatures is often sufficiently different to make meaningful comparison impossible.

Occasionally, it is not clear why two groups of workers obtained very different sets of results at the same temperature and pressure, although both sets of results were obtained by reliable methods and are internally consistent. In such cases, sometimes an incorrect assessment has been given. There are several examples where two or more sets of data have been classified as tentative although the sets are mutually inconsistent.

Many high pressure solubility data have been published in a smoothed form. Such data are particularly difficult to evaluate, and unless specifically discussed by the authors, the estimated error on such values can only be regarded as an "informed guess".

Many of the high pressure solubility data have been obtained in a more general study of high pressure vapor-liquid equilibrium. In such cases a note is included to indicate that additional vapor-liquid equilibrium data are given in the source. Since the evaluation is for the compiled data, it is possible that the solubility data are given a classification which is better than that which would be given for the complete vapor-liquid data (or vice versa). For example, it is difficult to determine coexisting liquid and vapor compositions near the critical point of a mixture using some widely used experimental techniques which yield accurate high pressure solubility data. For example, conventional methods of analysis may give results with an expected error which would be regarded as sufficiently small for vapor-liquid equilibrium data but an order of magnitude too large for acceptable high pressure gas-liquid solubility.

It is occasionally possible to evaluate data on mixtures of a given substance with a member of a homologous series by considering all the available data for the given substance with other members of the homologous series. In this study the use of such a technique has been very limited.

The estimated error is often omitted in the original article and sometimes the errors quoted do not cover all the variables. In order to increase the usefulness of the compiled tables estimated errors have been included even when absent from the original article. If the error on *any* variable has been inserted by the compiler this has been noted.

PURITY OF MATERIALS

The purity of materials has been quoted in the compiled tables where given in the original publication. The solubility is usually more sensitive to impurities in the gaseous component than to liquid impurities in the liquid component. However, the most important impurities are traces of a gas dissolved in the liquid. Inadequate degassing of the absorbing liquid is probably the most often overlooked serious source of error in gas solubility measurements.

APPARATUS AND PROCEDURES

In the compiled tables brief mention is made of the apparatus and procedure. There are several reviews on experimental methods of determining gas solubilities and these are given in References 1-7.

METHODS OF EXPRESSING GAS SOLUBILITIES

Because gas solubilities are important for many different scientific and engineering problems, they have been expressed in a great many ways:

The Mole Fraction, x(g)

The mole fraction solubility for a binary system is given by:

$$x(g) = \frac{n(g)}{n(g) + n(1)}$$

$$= \frac{W(g)/M(g)}{[W(g)/M(g)] + [W(1)/M(1)]}$$

here n is the number of moles of a substance (an amount of substance), W is the mass of a substance, and M is the molecular mass. To be unambiguous, the partial pressure of the gas (or the total pressure) and the temperature of measurement must be specified.

The Weight Per Cent Solubility, wt%

For a binary system this is given by

$$wt% = 100 W(g)/[W(g) + W(1)]$$

where W is the weight of substance. As in the case of mole fraction, the pressure (partial or total) and the temperature must be specified. The weight per cent solubility is related to the mole fraction solubility by

$$x(g) = \frac{[wt\$/M(g)]}{[wt\$/M(g)] + [(100 - wt\$)/M(1)]}$$

The Weight Solubility, $C_{\overline{W}}$

The weight solubility is the number of moles of dissolved gas per gram of solvent when the partial pressure of gas is 1 atmosphere. The weight solubility is related to the mole fraction solubility at one atmosphere partial pressure by

$$x(g) \text{ (partial pressure 1 atm)} = \frac{C_{w}M(1)}{1 + C_{w}M(1)}$$

where M(1) is the molecular weight of the solvent.

The Moles Per Unit Volume Solubility, n

Often for multicomponent systems the density of the liquid mixture is not known and the solubility is quoted as moles of gas per unit volume of liquid mixture. This is related to the mole fraction solubility by

$$x = \frac{n v^{0}(1)}{1 + n v^{0}(1)}$$

where $v^{O}(1)$ is the molar volume of the liquid component.

The Bunsen Coefficient, a

The Bunsen coefficient is defined as the volume of gas reduced to 273.15K and 1 atmosphere pressure which is absorbed by unit volume of solvent (at the temperature of measurement) under a partial pressure of 1 atmosphere. If ideal gas behavior and Henry's law is assumed to be obeyed,

$$\alpha = \frac{V(g)}{V(1)} \frac{273.15}{T}$$

where V(g) is the volume of gas absorbed and V(1) is the original (starting) volume of absorbing solvent. The mole fraction solubility is related to the Bunsen coefficient by

tity is related to the Bunsen of
$$x(g, 1 \text{ atm}) = \frac{\alpha}{\alpha + \frac{273.15}{T} \frac{v^{\circ}(g)}{v^{\circ}(1)}}$$

where $v^{O}(g)$ and $v^{O}(1)$ are the molar volumes of gas and solvent at a pressure of one atmosphere. If the gas is ideal,

$$x(g) = \frac{\alpha}{\alpha + \frac{273.15R}{V^{0}(1)}}$$

Real gases do not follow the ideal gas law and it is important to establish the real gas law used for calculating α in the original publication and to make the necessary adjustments when calculating the mole fraction solubility.

The Kuenen Coefficient, S

This is the volume of gas, reduced to 273.15K and 1 atmosphere pressure, dissolved at a partial pressure of gas of 1 atmosphere by 1 gram of solvent.

The Ostwald Coefficient, L

The Ostwald coefficient, L, is defined at the ratio of the volume of gas absorbed to the volume of the absorbing liquid, all measured at the same temperature.

$$L = \frac{V(q)}{V(1)}$$

If the gas is ideal and Henry's Law is applicable, the Ostwald coefficient is independent of the partial pressure of the gas. It is necessary, in practice, to state the temperature and total pressure for which the Ostwald coefficient is measured. The mole fraction solubility, x, is related to the Ostwald coefficient by

$$x(g) = \frac{RT}{P(g) L v^{O}(1)} + 1$$

where P is the partial pressure of gas. The mole fraction solubility will be at a partial pressure of P(g).

The Absorption Coefficient, 8

There are several "absorption coefficients", the most commonly used one being defined as the volume of gas, reduced to 273.15K and 1 atmosphere, absorbed per unit volume of liquid when the total pressure is 1 atmosphere. β is related to the Bunsen coefficient by

$$\beta = \alpha (1-P(1))$$

where P(1) is the partial pressure of the liquid in atmosphere.

The Henry's Law Contant

A generally used formulation of Henry's Law may be expressed as

$$P(g) = K_H x(g)$$

where K_H is the Henry's Law constant and x the mole fraction solubility. Other formulations are

$$P(g) = K_2C(1)$$

or

$$C(g) = K_CC(1)$$

where K_2 and K_c are constants, C the concentration, and (1) and (g) refer to the liquid and gas phases. Unfortunately, K_H , K_2 and K_C are all sometimes referred to as Henry's Law constants. Henry's Law is a limiting law but can sometimes be used for converting solubility data from the experimental pressure to a partial gas pressure of 1 atmosphere, provided the mole fraction of the gas in the liquid is small, and that the difference in pressures is small. Great caution must be exercised in using Henry's Law.

The Mole Ratio, N

The mole ratio, N, is defined by

$$N = n(g)/n(1)$$

Table 1 contains a presentation of the most commonly used inter-conversions not already discussed.

For gas solubilities greater than about 0.01 mole fraction at a partial pressure of 1 atmosphere there are several additional factors which must be taken into account to unambiguously report gas solubilities. Solution densities or the partial molar volume of gases must be known. Corrections should be made for the possible non-ideality of the gas or the non-applicability of Henry's Law.

TABLE 1. Interconversion of parameters used for reporting solubility.

L =
$$\alpha(T/273.15)$$

 $C_{w} = \alpha/v_{o}\rho$
 $K_{H} = \frac{17.033 \times 10^{6} \rho(\text{soln})}{\alpha M(1)} + 760$
L = $C_{w} v_{t,gas} \rho$

where v_o is the molal volume of the gas in cm³ mol⁻¹ at 0°C, ρ the density of the solvent at the temperature of the measurement, ρ_{soln} the density of the solution at the temperature of the measurement, and $v_{t,gas}$ the molal volume of the gas (cm³ mol⁻¹) at the temperature of the measurement.

LVALUATOR:

Rubin Battino, Chemistry Department, Wright State University, Dayton, OH 45435 USA,

June 1987

CRITICAL EVALUATION:

From Henry in 1803 to Rettich et al. in 1982 there have been only eleven papers reporting on the solubility of carbon monoxide, a common and biologically important gas, in water at a partial pressure of gas of 101.3 kPa. The Editor of this volume considered both Henry's work (1) and Cassuto's work (2) to be too imprecise to even compile and this evaluator agrees with that judgement. A value from a paper by Lubarsch (3) was also not compiled because of unclear experimental conditions. The data of Jung et al. (4) were presented only in graphical form, and are considered in the evaluation of high pressure solubilities in water.

The modern measurements of Rettich et al. (5) are of high-precision (a standard deviation of 0.04%) and are the current standard against which we are evaluating all other measurements of this system. Bunsen's work (6) is mainly of historical interest, being on the average 6% low. There were three papers published around the turn of the century. Just's two values (7) are about 8% low. Christoff's single value (8) is about 3% low. It appears on a data sheet for water and sulfuric acid mixtures. Winkler's extensive data (9) are about 3% low on the average. His precision is about 1% and his data go 25 K higher than those of Rettich et al., but in the range where the two sets of data overlap the differences are too large to give Winkler's higher temperature measurements much weight. The only modern measurements are those of Power (10) and Power and Stegall (11). The single value of the first paper (10) is low by about 8%, and the three values in the second paper (11) range from 6% low by about 1% high (compared to Rettich et al.). The only reliable data which are currently available are those of Rettich et al. (5) and these are the data which we are recommending.

Rettich et al. (5) fit their data to the smoothing equation

 $\ln (H_{1,2}/Pa) = 126.753761 - 152.599953/(T/100 K) - 67.8429542 \ln (T/100 K) + 7.04595356 (T/100 K)$

with a standard deviation in terms of percentage of 0.043%.

 $H_{1,2}$ ($T,P_{s,2}$) is the Henry's coefficient at the thermodynamic temperature T and the saturation vapor pressure of the solvent $P_{s,2}$.

The following table gives smoothed <u>recommended</u> values at 5 K intervals from 273.15 to 328.15 K based on the above equation. Note that the mole fractions in the table are for 1 atm partial pressure of gas and that the standard state for the thermodynamic functions is also 1 atm. The

limiting value of the Ostwald coefficient, L^∞ , is defined by

$$L^{\infty} = \lim (c_i^{L}/c_i^{V}) \text{ equil}$$

$$c_i^{L} \rightarrow 0$$

where the c's are molar concentrations of the gas in the liquid or gas phase as indicated by the superscript.

The mole fraction solubility at 101.325 kPa carbon monoxide partial pressure was calculated by the compiler using a carbon monoxide molar volume of 22,400 cm 3 (STP) mol $^{-1}$.

The Ostwald coefficients and Kelvin temperatures were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Bunsen method.

The second paper cited is a complete English translation of the first paper. The third paper is a long abstract of the first paper. These data were published two other places by Bunsen (ref 1 and 2).

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid on magnesium formate
- (2) Water. Distilled.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.1$ $\delta \alpha/\alpha = \pm 0.03 - 0.05$ (compiler)

293.2	2.08	2.41	2.586
293.2	1.90	2.20	2.404

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD APPARATUS / PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoside. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Water. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

- e Mole fraction calculated for unit fugacity of 1 atm (101.325 kPa).

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus used was modelled after that of Benson, Krause, and Peterson (ref 1). Degassed water is flowed in a thin film over the surface of a one dm³ sphere to contact the gas. After equilibrium is attained the solution is sealed in a chamber of calibrated volume. The dissolved gas is extracted and its amount determined by a direct PVT Measurement. A sample of the gas phase is analyzed in an identical manner. From the results, the saturation pressure of the solvent and Henry's constant are calculated in a thermodynamically rigorous manner, applying all nonideal corrections.

The authors smoothing equation, which fits their data to 0.04 %, is:

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson Co., Research grade. 99.99 mol per cent minimum purity.
- (2) Water. Reverse osmosis "house distilled" water was further purified by passage through a series of Illco-Way ion-exchangers and a 1.2 μm pore size Millipore filter. Water resistivity greater than 5 x 10⁴ Ωm.

CRITICAL EVALUATION:

The high pressure solubility of carbon monoxide in water

Four groups of workers have measured the solubility of carbon monoxide in water at temperatures up to 573 K and pressures between 0.1 and 9 MPa. The data of Jung et al.(1) are the most comprehensive, covering 298-573 K and pressures up to 9 MPa. In the evaluator's opinion, they are also the most reliable as demonstrated in the comparison table 1 below. Unfortunately their original paper gave results only in the form of graphs from which the numerical data have been compiled. The data sheet should be consulted for details.

The values from Granzhan (2) at 5.06 MPa and 298-348 K appear to be high by about a factor of two, and should be rejected. The values from Dake and Chaudhari (3) at 2-6.3 MPa do not show a minimum around 348 K as expected, and compare favourably with those of Jung et al.only around 448 K. The data of Taqui Khan and Halligudi (4) at 3 MPa appear to be too low except for the value at 403.15 K.

For comparison in the following table, all values were converted on the data sheets to the mol fraction solubility at 1 MPa, assuming the validity of Henry's law. This assumption appears to be justified from the experimental work for the pressure range of the measurements.

Table 1. Comparison of data from different sources on the solubility of carbon monoxide in water

For each temperature the authors measured the solubility (mole fraction and Kuenen coefficient) as a function of pressure up to about 9 MPa (graphical presentation only). From the low-pressure results they determined Henry's Law constants and plotted K_H against temperature. From such a graph (figure 9 of the source publication) the compiler read the K_H and T data, and then calculated mol fractions for a reference pressure of 1MPa, assuming $p_1 = K_H \times_1$.

CRITICAL EVALUATION:

AN EVALUATION OF THE SOLUBILITY OF CARBON MONOXIDE IN SEA WATER

There are only two reports of the solubility of carbon monoxide in sea water (1, 2). The two reports both cover a wide range of temperatures, but the sea water salinity range is limited in both reports. The main differences between the two, however, are in their technique and the partial pressure of carbon monoxide used. Douglas (1) reports 48 solubility measurements for three chlorinities (15.38, 18.60, 20.99‰) for several different temperatures between 274.03 and 202.85 K. Chlorinity can be related to salinity through the expression Salinity (%) = 1.80655 x Chlorinity (‰). The carbon monoxide solubility measurements of Douglas are estimated to have an accuracy of 0.6% and calculations of the relative standard deviation (RSD) at each temperature varied from 0.05 - 0.55% with an average RSD of 0.23%. There was no systematic variation in the data with either chlorinity or temperature and the RSD of the data at each chlorinity was identical to the average of the data set, 0.23%. Schmidt (2) reports 24 solubility values over the temperature range of 272.71-297.42 K at a salinity of 31.6% (chlorinity = 17.5%). The carbon monoxide solubility measurements of Schmidt (1) are estimated to have a standard error of 7%. The difference between the methods used by Schmidt (2) and Douglas (1) are significant. Douglas (1) used a modification of the microgasometric technique of Scholander (3) and a carbon monoxide partial pressure of 101.325 kPa. Schmidt (2) saturated sea water using a glass purging cylinder and a standard gas with a carbon monoxide partial pressure of $9.7 \times 10^{-4} \text{ kPa}$ (9.6 ppmv). The levels of carbon monoxide in the equilibrated sea water were too low to measure volumetrically and were measured with a HgO technique (4). The extrapolation from these extremely low pressures to 101.325 kPa for the Bunsen solubility determination probably causes the high error in the method. As a result of this error, the data of Schmidt (2) are not considered reliable.

The solubility data of Douglas (1) is of high enough precision that it can be used to derive a predictive equation. Douglas' data were combined with the distilled water data of Winkler (5), without weighting, to derive a smoothing equation. The combined data sets have been fitted (6) by the method of least squares to an equation developed by Weiss (7) which expresses solubility as the natural logarithm of the Bunsen coefficient, α , and is consistent with both the integrated form of the van't Hoff equation and the Setchenow salt effect relation. The equation for carbon monoxide is valid from 273.15 to 303.15 K and a salinity range, S, of 0 to 40‰. The smooth equation reproduced the combined carbon monoxide data with a root-mean-square deviation of 1.3 X 10^{-4} units (~ 0.42%). The equation is

 $\ln \alpha = -47.6148 + 69.5068 (100/T) + 18.7397 \ln (T/100)$

+ S $[0.045657 - 0.040721 (T/100) + 0.0079700 (T/100)^{2}]$

where S is the salinity in parts per thousand. Wiesenburg and Guinasso (6) give an extensive table of carbon monoxide Bunsen coefficients calculated from the above equation.

Although the Bunsen solubility coefficients are well defined by the above equation, for practical purposes, oceanographers require the atmospheric equilibrium solubility values in their work. Weiss (7) has proposed an equation similar to the above which expresses the atmospheric equilibrium solubility from moist air at 1 atm total pressure, in units of volume (STP) dm^{-3} , as a function of salinity and temperature. In working with samples from the depths of the ocean, it is also advantageous to express

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Sea Water

EVALUATOR:

CRITICAL EVALUATION:

atmospheric solubilities in terms of mol kg^{-1} , which are pressure and temperature independent (7, 8). Weiss' atmospheric solubility equation is based on the assumption of a constant atmospheric concentration of carbon monoxide. Since carbon monoxide is variable in the atmosphere, Weiss' (7) equation has been modified (6) to include atmospheric concentration as a variable. The combined data sets for carbon monoxide (1,6) have been fitted (6) to the equations

 $\ln c_1/nl dm^{-3} = \ln f_g - 169.4951 + 263.5657 (100/T)$

- + 159.2552 ln (T/100) 25.4967 (T/100)
 - + S [$0.051198 0.044591 (T/100) + 0.0086462 (T/100)^2$]

 $\ln m_1/n \mod kg^{-1} = \ln f_g - 175.6092 + 267.6796 (100/T)$

- + 161.0862 ln (T/100) 25.6218 (T/100)
- + S [$0.046103 0.041767 (T/100) + 0.0081890 (T/100)^2$]

where fg is the mole fraction of carbon monoxide in dry air. In these calculations carbon monoxide was assumed to be an ideal gas. Vapor pressure for pure water was calculated using the equation of Bridgeman and Aldrich (9) and corrected for salinity effects using the expression of Robinson (10). Knudsen's (11) formula was used to calculate densities. These two equations can be used to measure the atmospheric equilibrium solubility of carbon monoxide under any given conditions of temperature, salinity, and atmospheric concentration. Using an atmospheric carbon monoxide mole fraction of 0.11 x 10^{-6} (12), the equations reproduce the individual calculated atmospheric solubilities with a root-mean-square deviation of 0.45%.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Solubility determinations were made using the Scholander microgasometric technique as modified by Douglas (1). Gas-free sea water is brought into contact with pure carbon monoxide in a reaction vessel with a volume capable of accommodating 8 ml of water (2). The vessel is operated in a water bath in a constant temperature room. Rapid mechanical shaking for 30 min. allowed equilibration between the carbon monoxide and sea water. The amount of gas absorbed and the volume of sea water were measured volumetrically with a micrometer buret. Bunsen solubility coefficients were calculated from the observed volumes.

SOURCE AND PURITY OF MATERIALS:

- Carbon monoxide. Source not given. Purity determined to be at least 99.7% by one method and >99% by another.
- Sea Water. Gas-free sea water was obtained by vacuum extraction over mercury, millipore filtered and stored at 2770K.

ESTIMATED ERROR:

 $\delta T/K = 0.02$ $\delta C1/O/OO = 0.05$

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Solubility determinations were made using a 3 L glass purging cylinder jacketed by a water bath for temperature control. The sea water was purged with a very low partial pressure mixture of CO and H₂ at a flow rate of 1 L min⁻¹ for 30 min. A 0.2 L sample of equilibrated water was sucked into an evacuated sample cylinder and equilibrated with COfree air at 1 atm. The water volume and air volume were measured volumetrically. The CO content of the equilibrated air was determined using the HgO method (1,2). This value was used along with the volumes of air and water in the sample cylinder to calculate the solubility coefficient.

SOURCE AND PURITY OF MATERIALS:

CRITICAL EVALUATION:

Few workers have measured the solubility of carbon monoxide in aqueous solutions of simple electrolytes. Two papers deal with sulfuric acid, and one with its sodium salt also. One recent paper contained some information about aqueous copper(I) chloride and magnesium chloride, but no comment can be made about this system because the report of this work by Anserova and Ksandrov (1) was not available outside the USSR at the time of requesting it.

Eight papers report more extensively on acetates, carbonates, and/or formates of copper(I) - ammonium solutions which have been used industrially at various times as absorbents for carbon monoxide gas.

1. Carbon monoxide + sulfuric acid [7664-93-9] + water

Christoff (2) measured the solubility of carbon monoxide at 293.15 K and 101.3 kPa in water, concentrated sulfuric acid, and in two mixtures of these substances. The values given on the data sheet may be accepted tentatively. The Sechenov salt effect parameters k_{SC} (= k_{SCL}) are 0.073

and 0.043 dm³ mol⁻¹ at $c_2 = 4.63$ and 9.52 mol dm⁻³ respectively.

Carbon monoxide + sodium sulfate [7757-82-6] + sulfuric acid [7664-93-9] + water

The single measurement at $298.15~\mathrm{K}$ by Kobe and Kenton (3) is classed as tentative.

 Carbon monoxide + cuprammonium carbonate or formate or acetate, + water.

Several solvent systems for carbon monoxide have been based upon the copper(I) - ammonia complex ion in solution, along with different oxoanions. Interest in these systems has stemmed from their use in absorbing carbon monoxide from gas streams at low temperature, and releasing it at high temperature. Applications range from the purification of hydrogen (made from carbon monoxide and steam) required to synthesise ammonia, to, more recently, the purification of carbon monoxide itself for catalytic conversion to a number of organic compounds of commercial importance.

The work of Hainsworth and Titus (4) in 1921 was the first detailed study. Two different cuprammonium carbonate solutions were investigated and a data sheet has been prepared although their paper gave results only in the form of graphs. Similar work was done by Larson and Teitsworth (5) a year later on carbonate and formate solutions. Data have been compiled for one of the formate solutions only. It was not possible to compile data on the other nine solutions studied by these authors, because, firstly, the data were given only as points on small-scale, crowded graphs, and, secondly, comparison of the available tabulated and graphed data revealed that the scales on the axes of these graphs were incorrectly calibrated.

Both of these studies were made at temperatures between 273 and 333 K, and partial pressures of carbon monoxide varied up to about 3.5 bar or 1.2 bar. The conclusion reached by these authors is that the absorption of carbon monoxide is proportional to the concentration of copper(I) in solution. When formate was substituted for carbonate the capacity of the solutions for gas absorption was unchanged. However formate inhibited precipitation of copper from the solution. The compiled data of these authors can be taken as tentative, but treated with caution.

March 1989

CRITICAL EVALUATION:

Another paper, by Balla Béla and Kineses Gyula (6), may be referred to for this copper carbonate/formate - ammonia system. Similar conclusions were reached about the equivalence of formate and carbonate so long as the ammonia content of the solutions was the same. No data sheet was compiled, however, because the results were presented only on a small scale graph. Partial pressures of gas were 1-10 atm.

Tsiklis and Kofman (7) investigated three solutions containing copper(I) and copper(II) along with ammonia and carbonate, at 273-333 K, and partial pressures of carbon monoxide of 0.1 to 10 bar. Similar work by Ivanov et al (8) at these temperatures and pressures included acetate along with carbonate in some solutions. The gas phase was carbon monoxide in mixture with hydrogen and nitrogen at a total pressure of about 300 bar. The data from these papers may also be taken as tentative. With a large number of variables in the compositions and concentrations of the solutions it is not possible to make exact comparisons between the results from different authors, and the individual data sheets must be consulted for details.

A consecutive series of papers by Ksandrov and Strongin (9) also dealt with this type of solvent system. Lactate was an additional anion included in the study. However, data have not been obtained from these Russian papers because they were inaccessible at the time of searching.

In addition to the above, Korbutova et al.(10) and Vylivok et al.(11) investigated the effects of composition and temperature on the solubility of carbon monoxide in several solutions containing copper(I), copper(II), ammonia, carbon dioxide, and acetic acid at 283-313 K and partial pressures up to 1 bar. These authors concluded that the reaction occurring in these solutions could be represented by the equation

$$[Cu(NH_3)_3H_20]^+ + CO + NH_3 \rightleftharpoons [Cu(NH_3)_4(H_20)CO]^+.$$

Vylivok et al. used a gas mixture of carbon monoxide with carbon dioxide and showed that the absorption of carbon dioxide into the solution affected its free ammonia content, and this in turn altered the carbon monoxide solubility, unless the ammonia in solution was present in excess. Unfortunately, meaningful data sheets could not be compiled from these papers because the units of solubility measurement and some of the conditions were not clearly stated.

25	298.15	99.54 99.54	0.39 0.38	0.0036	0.0039	

The solvent is a mixture of 800 g H₂O

200 g Na₂SO₄ (anhydrous)

40 ml H_2SO_A (Conc., 36 normal)

Thus the molality of the solution is

$$m_2/\text{mol kg}^{-1} = 0.90 (H_2SO_4)$$

 $m_3/\text{mol kg}^{-1} = 1.76 \text{ (Na}_2\text{SO}_4\text{)}$

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus is described in detail in an earlier paper (1). The apparatus consists of a gas buret, a pressure compensator, and a 200 cm³ absorption bulb and mercury leveling bulb. The absorption bulb is attached to a shaking mechanism.

The solvent and the gas are placed in the absorption bulb. The bulb is shaken until equilibrium is reached. The remaining gas is returned to the buret. The difference in the final and initial volumes is taken as the volume of gas absorbed.

AUXILIARY INFORMATION

METHOD APPARATUS / PROCEDURE:

Gas enclosed between two columns of mercury was equilibrated by bubbling through a sample $(6-10\ \text{cm}^3)$ of solvent over a period of several hours, while measurements of volume were made at the desired pressure.

Allowance was made for vapour pressure of the solvent. For pressures below 500 mmHg, the carbon monoxide was diluted with nitrogen, introducing a slight error. For temperatures above 40°C, a simpler version of the apparatus was used.

calculated by compiler

(+) authors state that the volume of gas absorbed was calculated for 0°C and 760mmHg; from evidence available compiler believes this to be the Bunsen coefficient.

Note: The above data are tabulated and plotted on graphs in source. Data for 9 other solvent compositions are given only on graphs. These could not be meaningfully compiled because careful comparison showed that the pressure axis in figure 3, and both axes in figure 2 have scales which are incorrectly calibrated.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Carbon monoxide was stirred magnetically into a 10 cm³ sample of solution in an absorption pipette, contained in a thermostatted water bath. Equilibrium was attained within a few minutes. The volume of gas absorbed was measured by manometer readings. Allowance was made for the vapour pressure of the solvent.

CRITICAL EVALUATION:

The complex salt, copper(I) tetrachloroaluminate(III), dissolved in an aromatic solvent, usually toluene, can specifically and reversibly absorb carbon monoxide. This system is the basis of the industrial COSORB method for purification of carbon monoxide (1), a method which has several operational and cost advantages over the older aqueous cuprous - ammonium salt solution systems referred to in the previous section of this volume. The solubility of carbon monoxide in this non-aqueous salt solution is therefore of some practical interest, and data have been compiled from three recently published papers.

Because of the different temperatures, pressures, and concentrations studied by the different authors, very limited comparison between their results has been possible, and no set of data can be recommended at this stage. Each should be taken very tentatively until further confirmation is available. An overall comparison shows that the solubility of carbon monoxide increases with pressure and with concentration of the copper salt, and decreases with temperature and with the amount of substitution on the benzene ring of the solvent molecule.

1. Copper(I) tetrachloroaluminate(III) + benzene; C₆H₆; [71-43-2].

Copper(I) tetrachloroaluminate(III) + 1,2-dimethylbenzene; C₈H₁₀; [95-47-6].

The data of Sato $et\ a1.(2)$ at 303 K are the only ones available for these systems.

Copper(I) tetrachloroaluminate(III) + toluene; C₇H₈; [108-88-3].

Sato et al.(2) and the Engineering Research Group of Chekiang University (3) have provided data for this solvent at about the same temperatures and pressures, 273-323 K and 0.3-1.4 atm. The salt concentrations used by the Chekiang Group appear to be much higher than those of Sato et al, and their Ostwald coefficients appear to be very high and could be in doubt. It is unfortunate that incomplete specification of all the variables makes a thorough comparison impossible. Korbutov et al.(4) also studied this solvent, at 313-353 K and at higher pressures of 0.2-1.2 MPa. The data sheet from their work contains two graphs taken from their paper. Appropriate extrapolation of some of their data to the conditions of the work of Sato et al.shows that some agreement exists between them, although this cannot be specified quantitatively.

Harai et al. (5) also investigated properties of this system, and showed that the addition of polystyrene to the solvent prevented any deterioration in its efficiency as an absorber of carbon monoxide, due to the presence of water in the solute gas streams. This was a comparative kinetic study, however, and no equilibrium solubilities of carbon monoxide were available. A recent paper by Budner and Morawiec (6) deals with absorption of carbon monoxide in a toluene solution of the cuprous aluminate salt along with biphenyl C_{1,2H,10}, and aniline, C_{6H5NH2}, over 293-363 K. Quantitative data for the solubility of carbon monoxide were not obtained from this paper either.

Bunsen coefficients calculated by compiler assuming ideal gas behaviour and that Henry's law applies.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Solvent was degassed by boiling. Carbon monoxide was mixed with dry nitrogen and saturated with solvent vapour, then stirred into the solvent at constant temperature. The pressure change was followed with a pressure sensor, and mass balances were calculated. From these, the total uptake of carbon monoxide by the solvent, and the solubility itself were calculated.

The apparatus is based on that of Loprest (1).

SOURCE AND PURITY OF MATERIALS:

- Carbon monoxide: from cylinder, passed through silica gel and activated alumina.
- (2) Benzene: dehydrated with sodium sulphate.
- (3) CuAlCl₄: reagent grade CuCl and AlCl₃ dissolved and homogenised by stirring.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Flowing deabsorbing method. The liquid absorbent weighed and added to absorption vessel of the bubbling type. The entire system evacuated. Gas was fed through drying tubes and a flowmeter to the thermostated absorption vessel. The gas(es) after absorption led to another flowmeter or to a gas collection chamber for analyses. Equilibrium established when the readings from the two flowmeters and CO% before and after absorption were the same. Deabsorption by raising temperature to <98°C. Deabsorbed gases collected and analysed for CO, by GC. Pressure measured with a Hg manometer. Solvent not degassed but caused virtually no error because of high solubility. Measurements for industrial purposes (1).

SOURCE AND PURITY OF MATERIALS:

CRITICAL EVALUATION:

Very few investigations have been made of the solubility of carbon monoxide in solvents consisting of water mixed with an organic compound. There are only three papers giving data to evaluate, for eight different solvent systems, each at pressures above 2 MPa. There is very limited scope for comparison between different sets of data, and it is not possible to recommend any values. Further work on these systems, and fresh work on other related ones, would be worthwhile.

1. Methanol [67-56-1] and water

Granzhan (1) measured the solubility at 298 K and 348 K for a pressure of 5.06 MPa. Dake and Chaudhari (2) covered 298-448K in their study, at a partial pressure of carbon monoxide of 2-6 MPa. The whole range of solvent composition was covered in each case.

Comparison between the two sets of data at 298 K and 348 K shows that Granzhan's values are about 10% higher than corresponding values from Dake and Chaudhari. It is probable that the data of Dake and Chaudhari are the more reliable, since their data for methanol and for water themselves as solvents for carbon monoxide at high pressures correspond better to those of other workers than do Granzhan's.

2. Ethanol [64-17-5] and water

Lubarsch (3) published a paper in 1889 on the solubility of carbon monoxide (and oxygen and hydrogen also) in water-ethanol mixtures at 293 K and 1 atm partial pressure. It was not possible to extract meaningful data from this paper because the experimental details were vague and the solubility units unclear.

The data of Dake and Chaudhari (2) on this system at 2-6 MPa and 298-448 K may be accepted tentatively.

3. Allyl alcohol (2-propen-1-ol) [107-18-6] and water

Taqui Khan and Halligudi (4) studied the solubility of carbon monoxide at a total pressure of 3.202 MPa between 373 K and 403 K over the whole range of composition of this solvent. Their data need to be used with caution since their values for carbon monoxide in water from this series of experiemnts deviated from other published data.

4. Acetic acid (ethanoic acid) [64-19-7] and water

In some respects the data of Granzhan (1) at 5.06 MPa and 298 K and 348 K complement those of Dake and Chaudhari (2) at 2-6 MPa and 298-448 K. However comparison shows that Granzhan's values are about 10% lower than corresponding ones from Dake and Chaudhari. It is the evaluator's opinion that the data of Dake and Chaudhari for this system can be accepted tentatively, although their values for acetic acid itself appear to be somewhat low, perhaps because the acetic acid was not totally free from water.

5. Propionic (propanoic) acid [79-09-4] and water

The data of Dake and Chaudhari (2) for this system may be accepted tentatively, but confirmation is highly desirable.

- 1. Carbon monoxide; CO; [630-08-0]

May 1989

CRITICAL EVALUATION:

6. Methyl acetate [79-20-9] and water

Granzhan's work (1) gives the only data for this system at 298 K and 348 K, and 5.06 MPa. The two solvent components themselves, and two mixtures were studied. Because the data on the individual components do not compare very favourably with other published data, the values are classed as doubtful.

- 7. Diethylamine (N-ethylethanamine) [109-89-7] and water
- 8. Triethylamine (N, N-diethylethanamine) [121-44-8] and water

Taqui Khan and Halligudi (4) measured the solubility of carbon monoxide in several mixtures of each of these amines with water at partial pressures near 3.2 MPa over 343-373 K. The composition range for triethylamine-water is confined to the water-rich region. All of the data for these systems need further confirmation because of the uncertainty which surrounds their values for water as solvent.

A Henry's solubility constant, $H/\mathrm{kmol}\ m^{-3}\ \mathrm{kPa}^{-1}$, was calculated by the authors, and data correlated within 4.3% with the following equation: (Note that this H is the inverse of the conventional Henry's constant)

 $\ln H = -11.16 - 199.6/T - 25.73x_2(1/298-1/T) + 3.543 \ln(1+x_2)$

AUXILIARY INFORMATION

METHOD APPARATUS/PROCEDURE:

A known volume of solvent is equilibrated for about 3 hours with gas to saturation under pressure in an autoclave of 2 dm³ capacity, maintained at the required temperature.

A known volume of gas-saturated solvent is withdrawn into a gas-burette at atmospheric pressure, where the volume of the desorbed gas is measured by displacement of gas-saturated water at constant temperature (1).

Vapour pressures of solvent mixtures are given, used to calculate partial pressure of gas in autoclave.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: generated by dehydration of formic acid; purity >99.5%.
- (2) Methanol: from BDH Laboratories, freshly distilled; purity >99%.
- (3) Water: distilled.

A Henry's solubility constant, $H/kmol\ m^{-3}\ kPa^{-1}$, was calculated by the authors, and data correlated within 3.8% with the following equation: (Note that this H is the inverse of the conventional Henry's constant)

 $\ln H = -11.11 - 211.0/T + 160.2x_2(1/298-1/T) + 3.447 \ln(1+x_2)$

AUXILIARY INFORMATION

METHOD 'APPARATUS / PROCEDURE:

A known volume of solvent is equilibrated for about 3 hours with gas to saturation under pressure in an autoclave of 2 dm³ capacity, maintained at the required temperature.

A known volume of gas-saturated solvent is withdrawn into a gas-burette at atmospheric pressure, where the volume of the desorbed gas is measured by displacement of gas-saturated water at constant temperature (1).

Vapour pressures of solvent mixtures are given, used to calculate partial pressure of gas in autoclave.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: generated by dehydration of formic acid; purity >99.5%.
- (2) Ethanol: from BDH Laboratories, freshly distilled; purity >99%.
- (3) Water: distilled.

ESTIMATED ERROR:

 $\delta S = \pm 3\%$ (authors)

The data correlated within 3.6% with the equation

 $\ln H = -11.82 - 249.23/T - 25.89x_2(1/303-1/T) + 3.52 \ln(1+x_2)$

Note that this H is the inverse of the conventional Henry's constant.

AUXILIARY INFORMATION

METHOD APPARATUS/PROCEDURE:

- A known volume of solvent is equilibrated for about 3 hours with gas under pressure in an autoclave of $300~{\rm cm}^3$ capacity at the required temperature.
- A known volume of gas-saturated solvent is withdrawn into a gas-burette at atmospheric pressure where the volume of gas is measured by displacement of gas-saturated water at constant temperature (1).

Corrections are made for vapour pressures of solvent mixtures, and for the solubility of the gas at atmospheric pressure.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: from British Oxygen Co, purity >99.6% by GC analysis.
- (2) Allyl alcohol: AR grade, distilled before use, purity >99.5% by GC analysis.
- (3) Water: distilled.

ESTIMATED ERROR:

 $\delta p_1 = 3 \text{ kPa}$

 $\delta T = 0.1 \text{ K}$

 $\delta H = \pm 3\%$ (authors)

CRITICAL EVALUATION:

The Solubility of Carbon Monoxide at a Partial Pressure of 101.3 kPa

in n-Alkanes

Some six laboratories (1,3-7) have contributed data on the solubility of carbon monoxide at pressures close to 1 atm in individual n-alkanes, and all but one included the temperature 298.15 K. There are in fact very few data for temperatures other than this.

From this evaluation of all the available data, it becomes clear that in almost all cases more work needs to be done to either confirm or extend what has been published on these systems. Some measurements have been made by other workers at higher partial pressures for a few of these, and for some other alkane solvents, which are evaluated in a later section of this volume. Comparisons with data in this section are not possible however, even by extrapolation, because in each case the temperatures are either much higher or much lower than those considered here.

The most comprehensive study is by Makranczy et al. (1), providing solubilities at 298.15 K for each of the n-alkanes of carbon number 5-16. Figure 1 shows the trend in their values and compares them with the other values which are available.

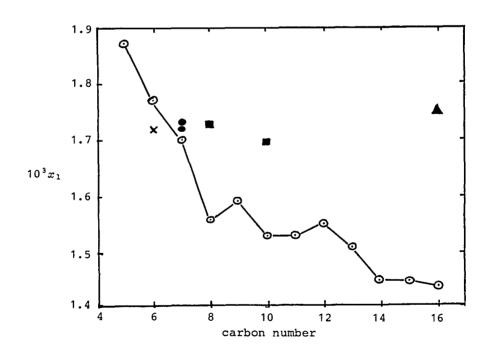

Figure 1 Mol fraction solubility of carbon monoxide in n-alkanes at 298.15 K and 101.3 kPa

- 2. n-Alkanes

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology. Bell Street, Dundee DD1 1HG, U.K.

May 1989

CRITICAL EVALUATION:

Unfortunately it appears that not too much confidence can be placed in these data of Makranczy et al., not only because of their deviations from the other values but also because their data on other gases, e.g. methane (2) in n-alkanes and on carbon monoxide in other solvents, e.g. alkanols (this volume) have shown similar discrepancies. Although proof cannot be furnished, it is the belief of this evaluator that the values of Makranczy et al for C_8 to C_{16} alkanes could be 10-20% too low.

Comments on the individual solvents are as follows.

1. Pentane; C₅H₁₂; [109-66-0]

The mol fraction solubility of 1.87 x 10^{-3} at 298.15 K due to Makranczy et al.(1) is the only value for this system. It would need to be checked.

2. Hexane; C₆H₁₄; [110-54-3]

The value from Makranczy, Patyi et al.(1) is about 3% higher than that given by Patyi, Makranczy et al.(3) a little later. Perhaps the lower value is more reliable because purity of reagents seems to have been checked more thoroughly. The experimental error in each measurement is about 3% according to the authors.

3. Heptane; C₇H₁₆; [142-85-5]

Gjaldbaek's two values (4) are about 1.5% higher than that of Makranczy et al. (1). These values may be accepted tentatively within the percentage error quoted on the data sheets.

4. Octane; C₈H₁₈; [111-65-9]

Decane; C₁₀H₂₂; [124-18-5]

For both of these solvents, the values of Wilcock et al. (5) at 298.15 K are about 10% higher than those of Makranczy et al. (1), and are to be preferred. In fact the data and the smoothing equations covering 283-313 K given on the data sheets from Wilcock et al. can be accepted tentatively for those solvents because this group's work is normally of a high standard.

5. Nonane; C₉H₂₀; [111-84-2]

For these solvents the values given by Makranczy et al. (1) show an irregular and unusual trend with increasing carbon number and may be in error, probably at least 10% low.

6. Hexadecane; $C_{16}H_{34}$; [544-76-3]

The value of Makranczy et al.(1) at 298.15 K is about 20% lower than that of Lin and Parcher (6). Although the latter value was obtained by a chromatographic method which can give rise to inaccuracies, it is much closer to the value of Tremper and Prausnitz (7) at the slightly higher temperature of 300 K. The data of Tremper and Prausnitz cover 300-475 K and may be accepted tentatively although confirmation is obviously necessary.

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology, Bell Street, Dundee DD1 1HG, U.K.

May 1989

CRITICAL EVALUATION:

Mixtures containing alkanes

Data are available for the solubility of carbon monoxide in petroleum at 283.15 K and 293.15 K from the year 1887 (8), in mineral oil ("Wemco A") at 298.15 K and 353.15 K (9), in "Kerosene A1" over 233-293 K (10), and in a paraffin oil (average relative molar mass 405) at 293.15 K (11). Whilst the compositions of these solvents are uncertain, the solubility values appear to be of an appropriate magnitude, and can be accepted as a good indication of the solubility of carbon monoxide in these types of solvent.

298.08	1.72	0.262	0.286

The mole fraction and Ostwald coefficient values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N2 trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

These values appear in the International Critical Tables, McGraw-Hill Book Co., New York and London, Vol.III, pp.261 - 270 where they are credited to an industrial report edited by A.H. Maude.

AUXILIARY INFORMATION

METHOD 'APPARATUS/PROCEDURE:

The apparatus consists of an 180 cm³ absorption bottle connected to a 100 cm³ gas buret. The absorption bottle sits in a thermostat, which is attached to a shaking machine.

A weighed sample of oil is introduced into the absorption vessel. The sample is degassed by vacuum, taking care to avoid excessive foaming. The gas is brought into the system. An initial buret reading is taken, and the shaker is started and reading taken every 5 minutes until 2 or 3 constant readings are obtained.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. No information
- (2) Mineral oil. A Pennsylvania base oil, 96 per cent saturated hydrocarbons, and distilling between 300 and 400°C. Density at 25°C = 0.840 and at 80°C = 0.800 g cm⁻³. As a commercial product the oil is known as "Wemco A".

EXPERIMENTAL VALUES:

Temperature Interval of Measurements	Carbon Monoxide Mol % Range	<i>K</i> πν/atm ¹ at 293.15 K	Enthalpy of Dissolution	Constant
T/K	$10^2 x_1 / \text{mol } $	293.13 K	$\Delta H/\text{kcal mol}^{-1}$	A
233.15-293.15	0.1	573	0.274	2.96

¹ log $(K\pi\nu/atm) = A - (\Delta H/cal mol^{-1})/(2.3R(T/K))$

The author's definitions are:

$$K = y_1/x_1 = \frac{\text{mole fraction gas in gas phase}}{\text{mole fraction gas in liquid phase,}}$$

 $\pi/atm = total pressure$

v = coefficient of fugacity

The function, $K\pi\nu/atm$, is equivalent to a Henry's constant in the form $H_{1,2}/atm = (f_1/atm)/x_1$ where f_1 is the fugacity.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The authors describe three methods:

- 1.A. [Saturat. n° 1]. A measure of
 the static pressure of satura tion in an apparatus which gave
 a precision of 10 15 %.
- 1.B. [Saturat. n° 2]. A measure of the static pressure of saturation in an apparatus which gave a precision of 2 - 5 %.
- [Chromato]. A Gas liquid chromatographic method estimated to have a precision of 2 - 5 %.
- [Anal. directe]. Direct analysis of the gaseous and liquid phases.

Method 1.B. was used for this system.

SOURCE AND PURITY OF MATERIALS:

- Carbon monoxide. Air Liquide. Contains N₂, purity 99 per cent.
- (2) Kerosene A-1.

CRITICAL EVALUATION:

The Solubility of Carbon Monoxide at High Pressures in Hydrocarbons

To complement the previous section on the solubility of carbon monoxide at a partial pressure of 1 atm in hydrocarbons, the following pages summarise, and evaluate where possible, solubilities where the partial pressure of carbon monoxide is significantly greater. For most of the studies this is in the range 0.5 - 5 MPa (5-50 atm). The solvents include saturated hydrocarbons of low and high molecular weights, some pure compounds and some mixtures, and there is also one study of an unsaturated hydrocarbon solvent.

1. Methane; CH₄; [74-82-8]

Of the four groups which have investigated the carbon monoxide - methane system, Toyama et al.(1) and Christiansen et al.(2) have provided the most comprehensive data, covering 113-186 K and 123-178 K respectively at pressures up to about 5 MPa. The agreement between these two data sets is very good, and the values given by each of these groups are recommended. The data of Cheung and Wang(3) cover the lower temperature range of 91-124 K at lower pressures of 0.026 - 0.52 Mpa, and are classed as tentative. The two values of Kerner and Knapp(4) at 140 K are in some disagreement with the recommended values, and should be regarded with less confidence.

Ostronov et al.(5) performed calculations on the phase equilibria of carbon monoxide and methane, and found satisfactory agreement with some published data at $0.68\ \text{MPa}$.

2. Propane; C₃H₈; [74-98-6]

The data of Cheung and Wang(3) cover temperatures of 86-129 K, and are classed as tentative. Work by Trust and Kurata(6) on the solubility of carbon monoxide and hydrogen together as gaseous solutes in propane at 223-323 K, may be referred to in Volume 5-6 of the Solubility Data Series, from which the solubilities of carbon monoxide in propane at these higher temperatures may be calculated.

With the increasing interest which has been shown by industrial and synthetic chemists in the interactions of carbon monoxide at high pressures with higher molecular weight hydrocarbons and their derivatives, there has been published, mostly within the past five years, several papers dealing with a variety of these systems. Some of the solvents are the single alkanes, $C_{8H_{18}}$, $C_{20H_{42}}$, $C_{28H_{58}}$ and $C_{36H_{74}}$. Others are complex mixtures containing alkanes of a range of carbon numbers, some of them commercial products, others involved in industrial processes. Those for which data sheets have been compiled are summarised in Table 1, where the solvents have been listed in order of increasing molecular weight. The general trend is that solubility decreases as molecular weight increases, although the special nature of some of the solvents can create anomalies from this principle.

It has been possible in only a few cases to make a critical evaluation because few studies have been duplicated under close enough conditions. Comments on individual systems follow after Table 1. The single alkanes are considered first, followed by the various mixtures.

3. Octane; C₈H₁₈; [111-65-9]

The work of Connolly (7), repeated and extended by Connolly and Kandalic(8), appears to be reliable and can be accepted tentatively for this solvent. In the earlier paper, results are given as K values, which are the ratios of the mol fraction of carbon monoxide in the gas and liquid phases. In the later paper, these mol fractions are actually listed.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Hydrocarbons

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology, Bell Street, Dundee DD1 1HG, UK.

May 1989

CRITICAL EVALUATION:

4. Eicosane; C₂₀H₄₂; [112-95-8]

Octacosane; C₂₈H₅₈; [630-02-4]

Hexatriacontane; C₃₆H₇₄; [630-06-8]

Huang et a1. (10) measured the solubility of carbon monoxide in these three heavy n-paraffins at 373-573 K and 1-5 MPa, as did Matsumato and Satterfield (14) for octacosane at 488-553 K and 0.5-0.8 MPa. Huang et a1. (10) also measured the solubility of "synthesis gas" (mixtures of three different compositions of carbon monoxide and hydrogen), in octacosane. There is very good agreement between the two sets of data for carbon monoxide in this solvent, and the values may be accepted tentatively. The values of Huang et a1. for the C₂₀ and C₃₆ paraffins are probably also reliable. At the temperatures studied, their solubilities increase with increasing molecular weight, which is however an unusual feature compared with the trend in Table 1.

5. C₆ - C₈ mixture of hydrocarbons.

Alekseeva et al.(16) measured the solubility of carbon monoxide (and of hydrogen also) at 5-15 MPa in "synthol" fractions in an investigation of starting materials and final products of the "oxo" process. These fractions were mixtures of hexane-hexene, heptane-heptene, and octane-octene. Hexyl alcohol was also investigated. Their results were given only on graphs, and temperature conditions were unclear, so no meaningful data sheets could be compiled.

6. Fischer-Tropsch fractions (alkane mixtures).

The work of Deimling et al. (9) on the solubility of carbon monoxide (and hydrogen) in C_5-C_{11} , $C_{11}-C_{22}$, and $C_{19}-C_{42}$ mixtures ("light", "medium", and "heavy" Fischer-Tropsch fractions) at 373-523 K and 0.5-4.5 MPa has shown that the solubility of carbon monoxide increases with temperature and decreases with increasing carbon number of the alkanes. They also found that the solubilities followed Henry's law very closely. Later work by this group (17, 18) showed that the solubilities in the "medium" and "heavy" fractions increased significantly when the wax was saturated with water.

To compile data sheets from their papers, solubility values had to be read from small-scale graphs. This obviously affects the accuracy of the data recorded on the sheets, but within the 5% possible error quoted by the authors, the data are classed as tentative. The values are consistent with those obtained by others for paraffin solvents of comparable molecular weights.

Deimling et al. (9) compared their data for the "light" and "medium" fractions with values computed from a nomograph by Zanker (19). This estimates solubilities of different gases in petroleum liquids by a method which depends on the application of the Clausius - Clapeyron equation, Henry's Law, and the ideal gas laws. Those computed values were in good agreement with the experimental data. A measurement by one member of the group (20) of the solubility of carbon monoxide at 298 K in "Soltrol", an isoparaffin mixture of the C_9-C_{12} range, was also shown to be consistent with their values for the "medium" fraction at higher temperatures.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Hydrocarbons

EVALUATOR:

Robert W. Cargill,

May 1989

CRITICAL EVALUATION:

7. Other hydrocarbon oils and waxes.

The values of Ledakowicz and Nowicki (12) for a paraffin oil solvent ($C_{15}-C_{36}$ mixture) at 471-534 K and 0.1-0.52 MPa appear to be consistent and compare favourably with values for other similar solvents. The same may be said for the values obtained by Peter and Weinert (11) for a paraffin wax of molecular weight 345 at 379-573 K and 0.1-0.5 MPa, and by Albal et al (13) for a "Gulfwax" of molecular weight 380 at 348-523 K and 1-3.2 MPa. Similarly the values of Huang et al. (10) for a "Mobil wax" of molecular weight 857 at 473-573 K and 1-5 MPa agree well with other available data. Additionally, their original paper develops a theoretical model which gives a good correlation with experimental values, and shows clearly how solubility decreases as molecular weight of the wax increases.

Finally, the work of Mehrotra and Svrcek (15) on a bitumen sample at 296-375 K and 3-9.7 MPa appears to be reliable, but like all other data considered in this section, would need further confirmation.

8. Isononenes; C_qH₁₈; [31387-92-5]

Tyvina et al.(21) have provided data for the solubility of carbon monoxide at 313-553 K and 5-30 MPa in this mixture of C_9 alkenes. The values may be used with caution, pending further investigations of this system.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Gas is passed through two stainlesssteel cells in series containing the solvent, in a thermostated nitrogen bath. The first cell is a presaturator, the second the equilibrium cell. A sample is taken from the equilibrium cell, and its pressure released. The solvent is solidified and weighed, and the liberated gas collected in a burette.

No undersaturation or supersaturation effects were noticed over a range of pressures.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson, purity >99.5%.
- (2) Eicosane. Aldrich, purity >99%.

ESTIMATED ERROR:

 $\delta T/K = 0.1$

 $\delta p/\text{kPa} = 5$

 $\delta x/x = \pm 0.02$ (compiler)

553.16	53.1	31.7	3.15

* calculated by compiler; inverse of Henry's constant, to give mol fraction solubility at 1 MPa partial pressure.

AUXILIARY INFORMATION

METHOD / APPARATUS / PROCEDURE:

Solvent is weighed into a 1 dm³ stainless steel bomb, wrapped in heating tapes. After flushing and reaching temperature equilibrium, gas is charged into the bomb at the required pressure (up to about 1 MPa).

Equilibrium is established by mechanical rocking for 2-3 hours.

Amount of gas absorbed is obtained from pressure measurements, and calculation of a mole balance.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson CP grade.
- (2) Octacosane. Humphrey Co. 99% pure.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Gas is passed through two stainlesssteel cells in series containing the solvent, in a thermostated nitrogen bath. The first cell is a presaturator, the second the equilibrium cell. A sample is taken from the equilibrium cell, and its pressure released. The solvent is solidified and weighed, and the liberated gas collected in a burette. Composition of the gas was found by chromatography.

No undersaturation or supersaturation effects were noticed over a range of pressures.

SOURCE AND PURITY OF MATERIALS:

- (1,2) Synthesis gas mixture.
 Matheson Gas Products
 (primary standards with
 specified compositions).
- (3) Octacosane. Alfa, purity >99%.

* Solubility given in source as volumetric ratio and weight percent. Volumetric ratio defined as volume of gas (at 0°C and 101.3 kPa) dissolved in a unit volume of gas saturated bitumen.

Solubility in g of gas per kg of solution was calculated by the compiler from the weight percent.

The viscosity and density values are for the gas-saturated bitumen at the temperature and pressure of the measurement.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Bitumen is saturated with gas under pressure by recirculating through a mixing cell until the viscosity becomes constant. Temperature is controlled in an air thermostat. Sample cells of 6 cm³ capacity are filled in the recirculating line. The volume of gas evolved from the sample is measured at 373 K and 1 bar using a mercury-filled Ruska pump. Details are in reference (1).

SOURCE AND PURITY OF MATERIALS:

- Carbon monoxide. No information given.
- (2) Bitumen. Gulf Canada Resources Inc. Sample diluted with toluene, filtered, vacuum distilled to remove water and toluene. Average molar mass 446.5 kg kmol⁻¹. Asphaltenes 11.8%; maltenes distillable <600°C 45.0%.

ESTIMATED ERROR:

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

A mechanically agitated vessel, 0.127 m diameter and 0.305 m height, equipped with flat-blade turbine agitator, is enclosed in a temperature regulated furnace. Preheated gas is fed into this reactor containing the solvent.

The solubility of the gas is calculated from the total pressure decrease during mixing, measured by a pressure transducer with its output registered on a high-speed chart recorder.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: no information.
- (2) Fischer-Tropsch liquid, medium fraction: alkanes C₁₁ - C₂₂, average molecular weight 201.5; density /kg m⁻³=874.3 - 0.3325 (T/K). Other details in source.
- (3) Water: no information.

ESTIMATED ERROR:

 $\delta c/c = \pm 5\%$ (compiler)

COMPONENTS: 1. Carbon monoxide; CO; [630-08-0] 2. Alkanes mixture C... - C..;

2. Alkanes mixture C₁₉ - C₄₄;
Fischer - Tropsch heavy fraction

3. Water; H₂O; [7732-18-5]

(a) extrapolated value

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Cyclic hydrocarbons

EVALUATOR:

Robert W. Cargill,
Department of Molecular
and Life Sciences,
Dundee Institute of Technology,
Bell Street, Dundee DD1 1HG, U.K.
May 1989

CRITICAL EVALUATION:

The solubility of carbon monoxide in some C_6 , C_7 , C_8 , and C_{12} cyclic hydrocarbons has only recently been measured. Three laboratories have produced these data, Battino et al., Patyi et al., and Tremper and Prausnitz. The partial pressure of the gas in all cases was near 101.3 kPa, and temperatures were near 298 K for all systems except the C_{12} solvent (1,1' bicyclohexyl) for which the temperature range was 300-475 K.

Only in the case of cyclohexane [110-82-7] is there more than one data set between which comparisons may be made. Here the datum of Patyi et al.(1) at 298.15 K is only 1.6% higher than that obtained from Wilhelm and Battino (2). The results from this latter group may be accepted tentatively, for temperatures of 283-309 K, along with the smoothing equation given on the data sheet, because the group is well respected for its thorough and accurate work.

A similar comment applies to the data for methylcyclohexane [108-87-2] (3), cis and trans 1,2 dimethylcyclohexane [2207-01-4] and [6876-23-9] (4), mixtures of cis and trans 1,3 and 1,4 dimethylcyclohexanes [2207-03-6], [638-04-0], [2207-04-7] and [624-29-3] (4), and cycloctane [292-64-8], (5). For each of these solvents the data sheets should be consulted, and cautions noted, when appropriate, about smoothing equations.

The data of Tremper and Prausnitz (6) on 1,1'bicyclohexyl [92-51-3] are probably reliable enough, but they must be accepted with caution in the absence of corroborating data.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to $500~\text{cm}^3$ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N₂ trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Linde Co. The minimum volume percent purity is 99.5.
- (2) Cyclohexane. Phillips Petroleum Co. Pure Grade. Distilled.

ESTIMATED ERROR:

313.00	1.305	0.1978	0.2266

The Bunsen coefficients were calculated by the compiler.

The solubility values were adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) by Henry's law.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N_2 trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by differences between the initial and final volumes in the buret The solvent is collected in a tared flask and weighed.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Aromatic hydrocarbons

EVALUATOR:

Robert W. Cargill,
Department of Molecular
and Life Sciences,
Dundee Institute of Technology,
Bell Street, Dundee DD1 1HG, U.K.

April 1989

CRITICAL EVALUATION:

The solubility of carbon monoxide in five aromatic hydrocarbons is considered in this evaluation. In all but three of the papers considered, pressures and temperatures were around ambient.

1. Benzene; C_6H_6 ; [71-43-2]

There are seven papers which report the solubility of carbon monoxide at a partial pressure of 101.3 kPa in benzene. The widest temperature range is covered by Horiuti (1), giving data over 285-334 K. These data are the ones recommended for this solvent between 285 and 315 K. They are represented by the equation

 $\ln x_1 = -6.2529 + 3.1556/(T/100 K).$

The solubility data of Just (2) at 293.15 and 298.15 K, and of Skirrow (3) at 298.2 K are low by 5-7%. The three values taken from graphs in the paper by Krauss and Gestrich (4) are about 3% low, whilst those of Patyi et a1. (5) and of Gjaldbaek (6) at 298.15 K, and of Byrne et a1. (7) at 310.64 K are all within 1% of the recommended values.

The only high pressure, high temperature study of the solubility of carbon monoxide in benzene carried out so far is by Connolly (8,9). Pressures of 0.7-10.5 MPa, and temperatures of 433-533 K were covered. Details are given in the data sheets. In the earlier paper, the data are reported as K values, which are the mole fractions of each component in the gas phase divided by its mole fraction in the liquid phase. In the later paper, where the pressure range was somewhat greater, actual mole fractions of carbon monoxide in the gas and liquid phases are given. The two sets of data complement each other and may be accepted tentatively.

2. Methylbenzene (toluene); C_7H_8 ; [108-88-3]

From the data in eight papers on the solubility of carbon monoxide at partial pressures near 101.3 kPa in methylbenzene, the recommended values are those of Field $et\ a1$ (10), given for T=283-313 K by the equation

 $\ln x_1 = -6.6251 - 1.5015/(T/100 \text{ K}).$

The data sheet from this work contains smoothed data which may be referred to with some confidence. From the smoothing equation, it can be calculated that for the transfer of carbon monoxide from the gas phase at 101.3 kPa to the infinitely dilute solution, $\Delta H_1^{\circ} = 1.25 \text{ kJ mol}^{-1}$, and $\Delta S_1^{\circ} = -55.1 \text{ J K}^{-1} \text{ mol}^{-1}$.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Aromatic hydrocarbons

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology. Bell Street, Dundee, DD1 1HG, U.K.

April 1989

CRITICAL EVALUATION:

Compared with this data set, the values of Just (2) are 2-3% too low, and those of Skirrow (3) and of Krauss and Gestrich (4) between 293 and 306 K are about 1% too low. The values of Krauss and Gestrich are taken from graphs, and their other values at 289.3 and 316.2 K may be 2% and 4% low respectively, whilst Gjaldbaek's data (6) at 298.15 K are 1-2% high.

The values obtained by Chen et al.(11) between 298 and 323 K show a much steeper increase with temperature than any of the other data. Little confidence can be placed in any of the values except the one at 303.15 K which is 1% higher than the interpolated value from Field et al. A single value at 303 K by Sato et al.(12) is also classed as doubtful, being about 6% lower than the others around 303 K. A very recent measurement by Lühring and Schumpe (13) gives a value at 293.2 K which is over 35% lower than any of the others at this temperature, and it has to be rejected.

Dimethylbenzene (xylene); C₈H₁₀; [1330-20-7]

The solubility of carbon monoxide in xylene was measured by Just (2) in 1901 and by Krauss and Gestrich (4) in 1977. In each of these cases it was assumed by the compilers of the data sheets that the xylene was a mixture of its isomers, although this was not clear from the original papers. On this basis, the more recent data are about 3% higher than corresponding values from Just, but all values on these data sheets must be treated with caution.

4. 1,2,4-Trimethylbenzene; C₉H₁₂; [95-63-6]

Krauss and Gestrich (4) measured the solubility of carbon monoxide in 1,2,4-trimethylbenzene over 289-314 K. The measurements require confirmation by other work, and it must be borne in mind that the data recorded were read off a graph in the original paper, making exact comparisons difficult.

5. Phenanthrene; C₁₄H₁₀; [85-01-8]

Matsumato and Satterfield (14) measured the solubility of carbon monoxide in phenanthrene at temperatures of 433-504 K and pressures of 0.5-0.8 MPa. The data require some further confirmation although there is no reason to doubt their validity.

Solvent mixtures including benzene or toluene.

The solubility of carbon monoxide at a partial pressure of 1 atm and at 298.2 K was measured by Skirrow (3) in a variety of solvent mixtures. Data sheets appear in this section for the solubilities in mixtures of benzene with 8 different substances, and in mixtures of toluene with 6 of these substances, viz. naphthalene, phenanthrene, α -naphthol, ethanoic acid, aniline, and nitrobenzene. β -Naphthol and methanol are the two additional substances which were studied mixed with benzene but not with toluene. In view of the reasonable accuracy of Skirrow's work, the data may be taken as a good indication of the solubility in the various mixtures.

Byrne et al. (7) measured the solubility of carbon monoxide at 1 atm and 310.6 K in benzene to which cholesterol or cephalin or lecithin had been added. "Salting-out" parameters are quoted for each additive, and solubilities of carbon monoxide in each additive itself have been obtained by extrapolation. Whilst these values must be taken very tentatively because of the extensive extrapolation, the experimental data are probably reliable within the 1-2% estimated on the data sheets.

	Mol Fraction	Bunsen	Ostwald
	104x1	Coefficient α/cm^3 (STP) cm ⁻³ atm ⁻¹	Coefficient L/cm ³ cm ⁻³
293.15		0.153	0.1645
298.15	6.24	0.156	0.1707

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Benzene. No information.

ESTIMATED ERROR:

333.15	7.465

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a gas buret, a solvent reservoir, and an absorption pipet. The volume of the pipet is determined at various meniscus heights by weighing a quantity of water. The meniscus height is read with a cathetometer.

The dry gas is introduced into the degassed solvent. The gas and solvent are mixed with a magnetic stirrer until saturation. Care is taken to prevent solvent vapor from mixing with the solute gas in the gas buret. The volume of gas is determined from the gas buret readings, the volume of solvent is determined from the meniscus height in the absorption pipet.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by dropping formic acid onto conc. H₂SO₄. The gas was passed through several wash solutions to remove CO₂ and O₂, dried by H₂SO₄ and P₂O₅.
- (2) Benzene. Merck. Extra pure and free of sulfur. Refluxed with sodium amalgam, distilled. Boiling point (760 mmHg) 80.18°C.

298.10	6.73	1.70	1.85
298.13	6.75	1.70	1.85

The mole fraction and Ostwald coefficient values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared from formic acid. 99.5% CO + 0.5% N₂.

COMPONENTS: (1) Carbon monoxide; CO; [630-08-0] (2) Benzene; C₆H₆; [71-43-2] Methylbenzene or toluene; C₇H₈; [108-88-3] VARIABLES: T/K = 298.2 p/kPa = 101.325 (1 atm) ORIGINAL MEASUREMENTS: Skirrow, F. W. Z. Phys. Chem., Stoechiom. Verwandtschafts1. 1902, 41, 139-60. PREPARED BY: H. L. Clever

EXPERIMENTAL VALUES:

Tempe	rature	Mol Fraction	Bunsen	Ostwald
t/°C	T/K	10 ⁴ x ₁	Coefficient $\alpha/\text{cm}^3 (\text{STP}) \text{cm}^{-3} \text{atm}^{-1}$	Coefficient L/cm ³ cm ⁻³
Benze	ne			
25.0	298.2	6.36	0.159	0.174
Methy	lbenzene	e		
25.0	298.2	7.94	0.167	0.182

The Bunsen coefficient and the mole fraction values were calculated by the compiler assuming ideal gas behavior. The values are adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of the liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorded gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the solvent volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Benzene.
 Methylbenzene.

No information.

ESTIMATED ERROR:

 $\delta L/\text{cm}^3 = \pm 0.001$

- 1. Just, G.
 - Z. Phys. Chem., Stoechiom. Verwandtschaftsl. 1901, 37, 342.

- (1) Carbon monoxide; CO; [630-08-0]
- (2) Methyl benzene or toluene; C_7H_8 ; [108-88-3]

ORIGINAL MEASUREMENTS:

Just, G.

Z. Phys. Chem., Stoechiom. Verwandtschaftsl. 1901, 37, 342-67.

VARIABLES:

T/K = 293.15, 298.15 $p_1/kPa = 101.325$ (1 atm)

PREPARED BY:

M. E. Derrick H. L. Clever

EXPERIMENTAL VALUES:

T/K	Mol Fraction	Bunsen Coefficient α/cm³(STP)cm-³atm-1	Ostwald Coefficient L/cm³cm-3
293.15	7.69	0.162	0.1742
298.15	7.89	0.166	0.1808

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Methyl benzene. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

 $p_1/kPa = 101.325$ (1 atm)

PREPARED BY:

J. Chr. Gjaldbaek

EXPERIMENTAL VALUES:

Coefficient α/cm^3 (STP) cm ⁻³ atm ⁻¹	Coefficient L/cm3cm-3
0.172	0.188 0.186
	0.172

The mole fraction and Ostwald coefficient values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared from formic acid (Merck, analytical reagent). 99.6 - 99.9% CO, the rest being atmospheric air.
- (2) Methylbenzene. Riedel-de-Haën. Analytical reagent. Fractionated by distillation. B.p. (760 mmHg)/°C = 110.75 - 110.80, refractive index n_D(25.1°C) = 1.4936 - 1.4938.

283.15	7.81	
293.15	7.95	
298.15	8.02	
303.15	8.08	
313.15	8.21	

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to $500~\rm{cm}^3$ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N_2 trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Either Matheson Co., Inc. or Air Products and Chemicals, Inc. Purest grade available, minimum purity greater than 99 mole per cent.
- (2) Methylbenzene. Phillips Petroleum. Pure Grade. Distilled.

ESTIMATED ERROR:

Chen, H.; Liu, M.; Zheng, L.; Zhu, Z. Zhejiang Daxue Xuebao, 1985, 19(1), 140-148 (Chinese).

VARIABLES:

Temperature = 298.15 - 323.15 K

PREPARED BY:

Shiqing Bo

EXPERIMENTAL VALUES:a

<i>T</i> /K	Henry's Constantb H2,1/atm	Mole fraction ^C at 1 atm P_{CO} , $10^{+}x_{1}$
298.15	1295.72	7.72
303.15	1224.74	8.17
313.15	1165.25	8.58
323.15	1112.18	8.99

- a. Measured at atmospheric pressure.
- b. The data were used to obtain (by linear regression); $H_{2,1} = 2492.3 4.1649T$, based on which the calculated values have a maximum relative deviation of $\pm 2.71\%$.
- c. Calculated by compiler based on P_{CO} = $H_{2,1}$ x_{CO} .

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Volumetric method. Modified Novak and Conway (1) apparatus. Solvent degassed to its vapor pressure. Pressure measured with a mercury manometer. Solvent stirred with a magnetic stirrer. Gas circulated by a gas pump. Equilibrium established when constant readings of volume reached.

SOURCE AND PURITY OF MATERIALS:

- (1) Prepared by the authors, ca. 98% pure.
- (2) Hongzhou Chlorophyll Plant (China), analytical grade.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.1$ (absorption vessel) $\delta T/K = \pm 1.0$ (entire system)

303	69.87	0.159	7.60

Bunsen coefficient calculated by compiler.

Mol fraction calculated by compiler assuming density of toluene at 303 K = 0.8564 σ cm $^{-3}$.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Solvent was degassed by boiling. Carbon monoxide was mixed with dry nitrogen and saturated with solvent vapour, then stirred into the solvent at constant temperature. The pressure change was followed with a pressure sensor, and the solubility was calculated.

The apparatus is based on that of Loprest (1).

SOURCE AND PURITY OF MATERIALS:

- Carbon monoxide: from cylinder, passed through silica gel and activated alumina.
- (2) Toluene: dehydrated with sodium sulphate.

ESTIMATED ERROR:

 $\delta H/H = \pm 5\%$ (compiler)

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

A barometic method of measurement (reference 1). A glass vessel containing 349.6 cm³ liquid and 589.9 cm³ gas, divided by a perforated glass plate, was stirred magnetically. Liquid was previously degassed by evacuation. Dry gas was admitted, and the pressure decrease monitored by a micromanometer. Saturation was achieved within 3-6 minutes.

Reported value is mean of 3 determinations.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: no information
- (2) Toluene: from Merck, "highest available purity".

ESTIMATED ERROR:

 $\Delta T = + 0.1K$ $\delta x/x = \pm 2$ % (authors)

REFERENCES:

 Schumpe, A.; Quicker, G.; Deckwer, W.D. Adv. Biochem. Eng. 1982, 24, 1.

calculated by compiler, assuming ideal gas behaviour and that Henry's law is obeyed; also that the density of toluene at 293.2 K is 0.866 g cm $^{-3}$

ORIGINAL MEASUREMENTS:

Just, G.

Z. Phys. Chem., Stoechiom. Verwandtschaftsl. 1901, 37, 342-67.

VARIABLES:

T/K = 293.15, 298.15 $p_1/kPa = 101.325 (1 atm)$

PREPARED BY:

M. E. Derrick H. L. Clever

EXPERIMENTAL VALUES:

<i>T</i> /K	Mol Fraction	Bunsen Coefficient α/cm³(STP)cm-³atm-1	Ostwald Coefficient L/cm³cm-3
293.15	8.87	0.163	0.1744
298.15	8.95	0.163	0.1781

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

The compiler assumed the dimethylbenzene was a mixture of 40 per cent 1,3-dimethylbenzene and 20 per cent each of 1,2-dimethylbenzene, 1,4-dimethylbenzene, and ethylbenzene. See Riddick, J. A.; Bunger, W. B. Organic Solvents 3rd Ed., Wiley-Interscience, New York, 1970, p. 614.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Dimethylbenzene. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

- Timofejew, W.
 Phys. Chem., Stoechiom.

 52, 275.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Dimethylbenzene or xylene (mixture?); C₈H₁₀; [1330-20-7]

ORIGINAL MEASUREMENTS:

Krauss, W.; Gestrich, W.

Chem.-Tech. (Heidelberg) 1977, 6, 513-516.

VARIABLES:

T/K = 288 - 317

PREPARED BY:

R. W. Cargill

EXPERIMENTAL VALUES:

Temperature T/K	Solubility* S/mol dm ⁻³ bar ⁻¹	Bunsen coefficient α/cm³ (STP)cm⁻³atm⁻¹	Mol fraction $10^4 x_1$
288.1	0.0075	0.168	9.18
301.9	0.0075	0.168	9.28
313.7	0.0075	0.168	9.38

^{*} read off graph in source.

The Bunsen coefficients and mole fractions (at 1 bar) were calculated by the compiler, assuming that the gas is ideal, and Henry's law is obeyed.

NOTE: The compiler assumed that the xylene was a mixture of 40% 1,3 dimethylbenzene and 20% each of the 1,2 and the 1,4 isomers, but this is not certain. The original paper, and an earlier reference (1) gives no clarification.

AUXILIARY INFORMATION

METHOD APPARATUS / PROCEDURE:

A known volume of gas was added to a known volume of liquid in a stirred equilibrium cell.

The equilibrium partial pressure was measured up to 2 bar. Diagram and details are given in source.

SOURCE AND PURITY OF MATERIALS:

No details given.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.05$; $\delta S/S = \pm 5\%$ (estimated by compiler)

* calculated by compiler; inverse of Henry's constant, to give mol fraction solubility at 1 MPa partial pressure.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Solvent is weighed into a 1 dm3 stainless steel bomb, wrapped in heating tapes. After flushing and reaching temperature equilibrium, gas is charged into the bomb at the required pressure (up to about 1 MPa).

Equilibrium is established by mechanical rocking for 2-3 hours.

Amount of gas absorbed is obtained from pressure measurements, and calculation of a mole balance.

SOURCE AND PURITY OF MATERIALS:

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the liquid volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO_2 .

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the liquid volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Nitrobenzene.
- (3) Benzene.

No information.

ESTIMATED ERROR:

 $\delta L/\text{cm}^3 = \pm 0.001 \text{ (Author)}$

REFERENCES:

^{*}Extrapolated carbon monoxide solubility in hypothetical liquid cholesterol.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid nitrogen trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

152 Alcohols

COMPONENTS:

1. Carbon monoxide; CO; [630-08-0]

2. Alcohols

EVALUATOR:

Robert W. Cargill,
Department of Molecular
and Life Sciences,
Dundee Institute of Technology,
Bell Street, Dundee DD1 1HG, UK.

March 1989

CRITICAL EVALUATION:

The Solubility of Carbon Monoxide in Alkanols at a Partial Pressure of 101.3 kPa.

Eight papers provide data on the solubility of carbon monoxide at 101.3 kPa in alcohols of carbon number C_1 to C_{12} . All of the straight-chain primary alkanols in the C_1 to C_{12} range are covered, along with a few secondary and branched-chain alcohols. One paper gives a result for cyclohexanol as solvent, and another includes a qualitative reference to glycerol.

In making comparisons it is noteworthy that all the measurements were made by volumetric methods, and the temperatures studied all included 298.15 K. Some data cover temperatures of 274-328 K.

Straight-chain Primary Alcohols.

To assist in the evaluation, the mole fraction solubilities at 298 K and 101.3 kPa partial pressure of carbon monoxide have been plotted on Figure 1 against carbon number of the alcohol. The smoothly increasing solubility with increasing carbon number is a feature which has been noticed for other gases in normal alcohols, according to an equation of the type due to Hayduk (1,2)

$$\ln x = b_1 + b_2 \ln C_n$$

From Figure 1 it is clear that over the range C_1 to C_{10} , there are two self-consistent but divergent lines which correlate two sets of data points. The lower set includes most of those by Makranczy et al., Skirrow's value, and Just's two values. The data of Makranczy et al. for C_{11} and C_{12} alcohols are about 15% too low to be included on this line. The upper set includes the data of Gjaldbaek and of Wilcock et al. and it is the evaluator's belief that this line is more reliable because these workers are very thorough in their experimental work, and measured solubilities over a wider range of temperatures obtaining more data points, which permits checking by interpolation, whereas Makranczy et al. and Skirrow measured the solubility at 298 K only, and Just at 293 and 298 K only.

Also, the work of Makranczy et al. on other gases dissolving in these alcohols has been found by other evaluators to show some significant deviations from other published data, e.g. hydrogen (3), oxygen (4), methane (2). Although conclusive proof is absent, several factors suggest that the solubilities of carbon monoxide measured by Makranczy et al. are about 10% too small over the C_1 to C_{10} range of alcohols.

		March 1989

CRITICAL EVALUATION:

Individual alcohols as solvents for carbon monoxide are now considered in turn.

1. Methanol; CH₄O; [67-56-1]

Just in 1901 (5) and Skirrow in 1902 (6) reported values for the solubility of carbon monoxide at 298.15 K, which are 1-2% lower than these of Makranczy et al. in 1979 (7). All of these values are about 12% lower than those obtained by Gjaldbaek in 1948. His data cover temperatures of 293-323 K, where the equation applies

$$\ln x_1 = -7.5979 - 0.8566/(T/100 K)$$

giving in Table 1 smoothed solubility values which can be tentatively accepted for this system. From the constants in the equation, it can be calculated that $\Delta H^0_1 = 710 \text{ J mol}^-$ and $\Delta S^0_1 = -63.2 \text{ J K}^-$ mol $^-$, for the transfer of one mole of carbon monoxide at a partial pressure of 101.3 kPa in the gas phase to the infinitely dilute solution.

3.85	21.13
	3.74 3.76 3.78 3.80 3.82 3.83

Brunner et al. (8) extrapolated data from their high pressure measurements on this system to give values of 10^4x_1 of 3.56 and 3.77 at 298.15 and 323.15 K respectively. These values are 5% and 2% lower than the corresponding values in Table 1. A very recent measurement by Luhring and Schumpe (16) at 293.2 K has given a solubility value which is also lower than Gjaldbaek's at 293.2 K, by about 10%. The evaluator believes, however, that confidence may be placed in Gjaldbaek's values over 293-323 K, although they appear to be high by comparison.

In a paper on gas-cleaning systems, Kruis and Scholz (9) gave a graphical representation of the solubility of carbon monoxide in methanol over 193 to 293 K. A line was drawn to include literature values along with some experimental results. However it was not clear what these were, and no reliable low temperature solubility data could be extracted. It can only be stated with caution that from this work it appears that the solubility increases almost linearly by about 54% as the temperature decreases from 293 to 193 K.

CRITICAL EVALUATION:

2. Ethanol; C₂H₆O; [64-17-5]

The data of Gjaldbaek (10) over the temperature range 293-323 K are the most comprehensive and consistent for this solvent. The data of Just (5) at 293 and 298 K, and of Skirrow (6) at 298 K are about 6% lower, and those of Makranczy et al. (7) are about 12% lower. Gjaldbaek's data can be tentatively accepted, given between 293 and 333 K by the equation

$$\ln x_1 = -7.5543 - 0.2053/(T/100 \text{ K})$$

Smoothed values are given in Table 2. From the constants in the equation, $\Delta H_{\gamma}^{O}=171~\mathrm{J~mol}^{-1}$ and $\Delta S_{\gamma}^{O}=-62.8~\mathrm{J~K}^{-1}$ mol for the transfer of one mole of the gas at a partial pressure of 101.3 kPa to the infinitely dilute solution.

Table 2: The Solubility of Carbon Monoxide in Ethanol:

tentative values of the mole fraction solubility and the partial molar Gibbs energy of solution at a partial pressure of 101.3 kPa.

<u>T/K</u>	10 ⁴ x _I	$\Delta G_1^{\circ}/kJ \text{ mol}^{-1}$
293.15	4.88	18.58
298.15	4.89	18.90
303.15	4.89	19.21
308.15	4.90	19.52
313.15	4.90	19.84
318.15	4.91	20.15
323.15	4.91	20.47

3. 1-Propanol; C₃H₈O; [71-23-8]

The 298 K value of Makranczy et al. (7) is about 5% lower than the value interpolated from Gjaldbaek's data (10) at 293, 308, and 323 K. The tentative mole faction solubilities, from Gjaldbaek, are given between 293 and 323 K by the equation

$$\ln x_1 = -7.4802 - 0.0771/(T/100 K),$$

from which smoothed values have been calculated in Table 3. From the constants in this equation, $\Delta H_1 = 64~\mathrm{J~mol}^{-1}$ and $\Delta S_1^{~0} = -62.2~\mathrm{J~K}^{-1}$ mol for the transfer of one mole of the gas at a partial pressure of 101.3 kPa to the infinitely dilute solution.

156 Alcohols

COMPONENTS:	EVALUATOR:
 Carbon monoxide; CO; [630-08-0] Alcohols 	Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology, Bell Street, Dundee DD1 1HG, UK. March 1989

CRITICAL EVALUATION:

Table 3: The Solubility of Carbon Monoxide in 1-Propanol:

tentative values of the mole fraction solubility and the partial molar Gibbs energy of solution at a partial pressure of 101.3 kPa.

	$\Delta G^{O}_{1}/kJ \text{ mol}^{-1}$
5.495	18.30
	18.61
	18.92
	19.23
	19.54
5.505	19.85
5.51	20.16

4. 2-Propanol; C₃H₈O; [67-63-0]

Gjaldbaek's measurements (10) at 293.1, 308.2, and 324.3 K are the only ones available for this system. They may be accepted tentatively. A smoothing equation and some calculated values are given on the data sheet. From that equation, it can be shown that ΔH_1 = 396 J mol and ΔS_1 = 60.3 J K mol for the transfer of one mole of the gas at 101.3 kPa partial pressure to the infinitely dilute solution.

5. 1-Butanol; C₄H₁₀O; [71-36-3]

The value of Makranczy et al. (7) at 298 K is about 12% lower than value of Gjaldbaek (10) interpolated from a spread of ten measurements between 292.9 and 323 K. Once again Gjaldbaek's data may be accepted tentatively. From 292.9 to 323 K they fit the equation

$$\ln x_1 = -7.5867 + 0.6180/(T/100 K)$$

and Table 4 gives some smoothed values. From the constants in this equation, $\Delta H_1^0 = -514~\mathrm{J}$ mol and $\Delta S_1^0 = -6.31~\mathrm{J}$ K mol for the transfer of one mole of the gas at 101.3 kPa partial pressure to the infinitely dilute solution.

Table 4: The Solubility of Carbon Monoxide in 1-Butanol: tentative values of the mole fraction solubility and the partial molar Gibbs energy of solution at a partial pressure of 101.3 kPa.

Bell Street, Dundee DD1 1HG, UK.

March 1989

CRITICAL EVALUATION:

6. 2-Butanol; C₄H₁₀O; [78-92-2]

Gjaldbaek's six values (10) between 293.2 and 323.4 K are the only ones available for this system. They may be accepted tentatively on the strength of the reliability of this worker's results on related solutions. A smoothing equation and some calculated values are given on the data sheet. From that equation it is found that $\Delta H_1^0 = 32 \text{ J mol}^{-1}$ and $\Delta S_1^0 = 61.1 \text{ J K}^{-1} \text{ mol}^{-1}$ for the transfer of one mole of gas at 101.3 kPa partial pressure to the infinitely dilute solution.

7. 2-Methyl-1-propanol; $C_4H_{10}O$; [78-83-1]

Two quite detailed studies of this system have been made, that of Gjaldbaek (10) in 1948 over 293-323 K (5 values) and that of Battino et al. (11) in 1971 over 274-328 K (9 values).

Each set of data is self consistent and smoothing equations for each are given in the two data sheets, but there is an increasing discrepancy between the two sets of data as the temperature goes from 300 to 330 K. Over this range the values of Battino et al. are from 2 to 7% lower, but show a temperature coefficient which is consistent from 274 to 330 K. On the evidence available it is not possible to entirely recommend any one of the data sets, and both may be used with caution. Smoothed values are given in Table 5, along with 2 values which have been extrapolated from values given by Tonner et al. (12) at 1000 kPa, assuming that Henry's law holds between 101 and 1000 kPa. If this assumption is correct, it indicates a preference for the data of Battino et al. Although many of the measurements by Tonner et al. are of doubtful accuracy (see the evaluation for carbon monoxide at high pressure in alcohols), the temperature coefficient of all the data for this system agrees with that of Battino et al. The wider temperature range, the reliability of the apparatus and its accessories, and the better accuracy of Battino et al. would confirm the choice of their data. From their smoothing equation, $A H_0 = -1.39 \, \text{kJ} \, \text{mol}^{-1} \, \text{and} \, A S_0 = -65.7 \, \text{J} \, \text{K}^{-1} \, \text{for the transfer of one} \, \text{mole} \, \text{of gas at 101.3 kPa} \, \text{partial pressure to the infinitely dilute} \, \text{solution}.$

March 1989

CRITICAL EVALUATION:

8. 2-Methyl-2-propanol; C₄H₁₀O; [75-65-0]

Gjaldbaek's data for this solvent may be accepted tentatively for the temperature interval 300-323 K, since they are in line with data on other similar systems. However they should be used with caution in the absence of any confirmatory evidence. A smoothing equation and some calculated values appear on the data sheet. From the equation, ΔH_1^{O} is 3.46 kJ moland ΔS_1^{O} is - 48.2 J K moland for the transfer of one mole of carbon monoxide at a partial pressure of 101.3 kPa to the infinitely dilute solution.

9. 1-Pentanol; C₅H₁₂O; [71-41-0]

Just's two measurements (5) of the solubility at 293.15 and 298.15 K, and Makranczy's (7) at 298.15 K are the only ones available for this system. Each should be used with great caution because it is likely that Just's values are several percent high, and Makranczy's about ten percent low (see figure 1).

10. 1-Hexanol; C₆H₁₄O; [111-27-3]

1-Heptanol; C₇H₁₆O; [111-70-6]

1-Nonanol; C₉H₂₀O; [143-08-8]

The values of Makranczy et a1.(7) at 298.15 K for these solvents are probably about 10% too low, and should be used with caution.

11. 1-Octanol; C₈H₁₈O; [111-87-5]

1-Decanol; C₁₀H₂₂O; [12-30-1]

The values of Wilcock et al. (13) are to be preferred to the lower values of Makranczy et al. (7) at 298 K. Some confirmatory data are required for these solvents before the values can be recommended.

12. 1-Undecanol; C₁₁H₂₄O; [112-42-5]

1-Dodecanol; C₁₂H₂₆O; [112-53-5]

The values of Makranczy et al. should be treated with great caution. Compared to the trends observed through the homologoeus series of n-alcohols, these values may be up to 20% too low (see Figure 1).

13. Cyclohexanol; C₆H₁₂O; [108-93-0]

The single measurement by Cauquil (14) at 299 K would need to be confirmed, but it appears to be of the appropriate magnitude.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Alcohols

March 1989

CRITICAL EVALUATION:

Solvent mixtures containing alcohols.

The solubility of carbon monoxide at 1 bar in a 1:1 molar mixture of 1-decanol and 1-dodecanol was measured at 293 K by Luther and Hiemenz (15). Other related solvent mixtures for which data are included in this section are methanol with glycerol, and methanol with chloroform, both due to Skirrow (6), at 1 bar and 298.2 K. All of these data appear to be of the correct magnitude, but would need further confirmation.

The Bunsen coefficient and the mole fraction values were calculated by the compiler assuming ideal gas behavior. The values are adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of the liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the solvent volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Methanol.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The degassed solvent and the gas are placed in a calibrated all-glass combined manometer and bulb enclosed in an air thermostat. The apparatus and contents are shaken until equilibrium. Mercury is used for calibration and as the confining liquid. The solvent is degassed in the apparatus.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Details in ref. 1,2.

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared from formic acid. 99.5% CO and 0.5% nitrogen (no CO₂ or O₂).
- (2) Ethanol. Dehydrated with magnesium. B.p./°C = 78.3, ρ/g cm⁻³(20°C) = 0.7892.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N₂ trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. The Matheson Co., Inc. Commercial grade stated to be better than 99 mol per cent.
- (2) 2-Methyl-l-propanol. Fisher Co. Certified grade (99 mol per cent).

COMPONENTS:

- (1) Carbon monoxide; CO; [124-38-9]
- (2) 1-Pentanol; C₅H₁₂O; [71-41-0]

ORIGINAL MEASUREMENTS:

Just, G.

Z. Phys. Chem., Stoechiom. Verwandtschafts1. 1901, 37, 342-67.

VARIABLES:

T/K = 293.15, 298.15 $p_1/kPa = 101.325 (1 atm)$

PREPARED BY:

M. E. Derrick H. L. Clever

EXPERIMENTAL VALUES:

<i>T</i> /K	Mol Fraction	Bunsen Coefficient \alpha/cm3 (STP) cm-3 atm-1	Ostwald Coefficient L/cm ³ cm ⁻³
293.15	7.71	0.159	0.1706
298.15	7.61	0.157	0.1714

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) 1-Pentanol. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

The author also reported the vapor pressure of the solvents.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the liquid volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) 1,2,3-Propanetriol.
- (3) Methanol.

CRITICAL EVALUATION:

The Solubility of Carbon Monoxide at High Pressures in Alcohols

Methanol; CH_AO; [67-56-1]

Five different papers contain data on the solubility of carbon monoxide in methanol at elevated pressures, and there is fairly good agreement among most of the values. The recommended data are those by Brunner et al.(1), which also cover the widest ranges of temperature and pressure. A comparison of the various conditions, and standardised values of the mol fraction solubility x_1 for a pressure of 1 MPa at 298 K from each paper, are given in Table 1. To obtain these standardised values of x_1 , each author's datum for the pressure p_1 nearest to 1 MPa was selected and the value divided by p_1 . This assumes that Henry's law is valid over this pressure range, an assumption borne out by an analysis of the pressure dependence of most of these data.

Table 1. Solubility of carbon monoxide in methanol

authors		<u>T/K</u>	p/MPa	10 ³ x ₁ at 1 MPa and 298 K
Krichevskii	(2)	298-413	6-30	3.16
Granzhan	(3)	298-348	5.06	3.28
Tonner	(6)	298,323	1-4	3.2
Dake	(4)	298-448	2-7	3.58
Brunner	(1)	298-498	2-100.7	3.56
Gjaldbaek	(5)	293-323	0.101	3.76

The data of Krichevskii et al. (2) and of Granzhan (3) are low by about 11% and 8% respectively compared to these of Brunner et al., which agree with the values of Dake and Chaudhari (4) over their pressure range of 2-7 MPa. Extrapolation of reliable measurements made by Gjaldbaek (5) at 101.3 kPa gives a somewhat higher value. Note that the data from Dake and Chaudhari appear in the water + organic solvent section earlier in this volume. The data of Tonner et al. (6) at 298 K and 323 K are classed as doubtful. The pressure dependence of their values appears to be too great. They obtained the solubilities by a chromatographic method, which is usually found to be unsuitable for accurate solubility measurements. The Henry's Law coefficients given on the data sheets from their work are based on data of low accuracy, and may be in error by up to 20%. It should also be noted that in the original paper a wrong multiplying constant was given, which has been corrected on the data sheet.

Krichevskii et al.(2) have provided data which may be accepted tentatively for three mixtures of carbon monoxide and hydrogen gases dissolving into methanol over 303-413 K, and at total pressures in the range 5-30.3 MPa.

Ethanol; C₂H₆O; [64-17-5]

There is some disagreement between the values from Tonner et al.(6) and those from Dake and Chaudhari (4) for this solvent. The former set of solubility values are higher but may be in error for reasons explained above (for methanol solvent). There is also an inconsistency on the data sheet derived from Tonner et al., where as T increases both K and x_1 at a given pressure decrease. Clearly this cannot be the case if, as they assume, $p = Kx_1$.

COMPONENTS:

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Alcohols

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology. Bell Street, Dundee DD1 1HG, U.K.

April 1989

CRITICAL EVALUATION:

The data of Dake and Chaudhari may be accepted tentatively for this solvent, although there is a possibility that their values could be a little low due to contamination of their samples of ethanol with water. These values appear on a data sheet in the earlier water + organic solvent section of this volume, since they are part of a wider study of the three-component system, carbon monoxide-ethanol-water.

1-Propanol; C₃H₈O; [71-23-8]

2-Propanol; C₃H₈O; [67-63-0]

1-Butanol; C₄H₁₀O; [71-36-3]

2-Butanol; C₄H₁₀O; [78-92-2]

2-Methyl-1-propanol; C₄H₁₀O; [78-83-1]

2-Methyl-2-propanol; C₄H₁₀O; [75-65-0]

The only data on carbon monoxide in these solvents at pressures above 1 atm are those of Tonner et al.(6). In the light of previous comments, and also because extrapolation of reliable values at 101.3 kPa to 1-4 MPa give significantly lower values in each case, it is believed that these data of Tonner et al are doubtful, probably about 20% too high.

2-Propen-1-ol (allyl alcohol); C₃H₆O; [107-18-6]

Taqui Khan and Halligudi (7) measured the solubility of carbon monoxide in mixtures of this unsaturated alcohol with water at about 3 MPa over 373-403 K. Data for solubility in allyl alcohol itself were obtained, and may be read in the water + organic solvent section of this volume. Like in other alcohols, the solubility of carbon monoxide increases with temperature under these conditions. The data should be used with great caution, however, because the values for carbon monoxide in water from this series of experiments differed somewhat from other published data.

Isodecanol; C₁₀H₂₂O; [25339-17-7]

C₁₂-C₁₅ alcohols mixture

Tyvina et a1. (8) and Naumova et a1. (9) studied the solubility of carbon monoxide in these solvents at 313-553 K and 5-30 MPa, in work related to investigations of the "oxo" process. Their results are in the form of mol fractions of the components in the liquid and vapor phases, and the values may be accepted tentatively although further confirmation is necessary for their unequivocal acceptance. Loktev et a1. (10) also measured the solubility of carbon monoxide along with hydrogen and ethyne in the C12-C15 alcohols mixture over similar temperatures and pressures by a different technique. Their data are given in Volume 5-6 of this series (11), and for carbon monoxide, the solubility values are similar to those of Naumova et a1., and help to confirm them.

If the English translation of the paper by Naumova et al.(9) is consulted, it should be noted that the pressure unit given is "gPa" which is a transliteration of a Russian symbol meaning hectopascal, i.e. 10 Pa. It was wrongly transcribed into GPa (to indicate gigapascal) in Chemical Abstracts 95, 176660.

Henry's constant, $K/kPa = (p_1/kPa)/x_1$.

The multiplying constant before Henry's constant appears to be in error. The compiler changed it from 10^{-3} to 10^{-5} .

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Solubility measurements were conducted by charging 200 cm³ of alcohol into a 300 cm³ capacity stainless steel autoclave which was then pressurized to the desired level from a cylinder of carbon monoxide. The autoclave was fitted with ancillary lines and valves to allow gas charging, sampling of the liquid phase, venting and draining.

Tests showed that about 2 minutes stirring brought the system to equilibrium. The liquid phase was sampled through a HPLC valve of 1 μ L internal volume. The sample was switched to a stream of hydrogen carrier gas (30 cm³ m⁻¹) where it vaporized and was carried into a Gow Mac gas chromatograph with a 6 ft column of Porapak Q and fitted with a thermal conductivity cell.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE: Two experimental methods were used. At medium to high pressures the dew and bubble points of a mixture of known composition were determined. Details of this method are given in source and ref. (1). At low mole fractions of methanol the composition of the mixture was determined by GC. In this technique several different methods were employed to obtain a representative sample. Details are given in the source.

SOURCE AND PURITY OF MATERIALS: 1. Messer-Griesheim sample, purity

- 99.97 mole per cent.
- Merck sample, purity 99.95 mole per cent; mass of water equal or less than 0.015 mass per cent.

ESTIMATED ERROR:

Solubility measurements were conducted by charging 200 cm³ of alcohol into a 300 cm³ capacity stainless steel autoclave which was then pressurized to the desired level from a cylinder of carbon monoxide. The autoclave was fitted with ancillary lines and valves to allow gas charging, sampling of the liquid phase, venting, and draining.

Tests showed that about 2 minutes stirring brought the system to equilibrium. The liquid phase was sampled through a HPLC valve of 1 μL internal volume. The sample was switched to a stream of hydrogen carrier gas (30 $\text{cm}^3~\text{m}^{-1}$) where it vaporized and was carried into a Gow Mac gas chromatograph with a 6 ft column of Porapak Q and fitted with a thermal conductivity cell.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson Co., Inc. c.p. grade.
- (2) 2-Propanol. Ajax Chemicals. 99.8 per cent purity.

ESTIMATED ERROR:

 $\delta T/K = \pm 1$ $\delta p/kPa = \pm 10$

 $\delta K/K = \pm 0.10$ (compiler)

- (1) Carbon monoxide; CO; [630-08-0]
- (2) 1-Butanol; C₄H₁₀O; [71-36-3]

ORIGINAL MEASUREMENTS:

a 239.0 in source; compiler believes it to be misprint for 289.0

calculated by compiler. Pressure units in source are "10³gPa" in English translation. This is not 10³GPa as given in *Chem. Abs.* 95, 176660 for this paper, but gPa is translation from Russian symbol which means hectopascal, i.e. 10²Pa.

Calculated by compiler from mol fraction of alcohols in each phase, given in source, assuming $x_1 + x_2 = 1$ and $y_1 + y_2 = 1$.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Ketones, acids, esters, ethers

March 1989

CRITICAL EVALUATION:

Acetone (2-propanone) [67-64-1]

The most extensive measurements of the solubility in acetone of carbon monoxide at a partial pressure of 1 atm were made by Horiuti (1), at temperatures between 193 K and 313 K. The solubility appears to pass through a minimum around 245 K. Just (2) provided data for 293.15 K and 298.15 K, and Skirrow (3) for 298.15 K. Compared with Horiuti's values at 298.15 K these are low by 14% and 8% respectively. In view of the thoroughness which characterises Horiuti's work, his values over 193-313 K can be accepted tentatively.

Skirrow's work (3) involved a rather extensive study of the solubility of carbon monoxide in solvent mixtures. In this section, data are given for solvents which were mixtures of acetone with naphthalene, phenanthrene, β -naphthol, chloroform, carbon disulfide, aniline, and nitrobenzene. The solubility values on the data sheets were stated by the author to have a possible error of 1%, but this is clearly overoptimistic in the light of comparisons with more recent data on the individual solvent components. The purity of these solvents as used in 1902 is also a matter of some doubt.

The trends in the solubilities are probably correct, but individual values need to be taken with caution.

Cyclohexanone [108-94-1]

Tyvina et al. (10) measured the solubility of carbon monoxide in this ketone over 313-513 K and at elevated pressures of 5-30 MPa. Their results are in the form of mol fractions of carbon monoxide in the liquid and vapour phases. There is no other work on this system with which to make comparisons, and the evaluator recommends that meantime the values be accepted tentatively. Further confirmatory evidence is obviously necessary.

Acetic acid (ethanoic acid) [64-19-7]

For a partial pressure of carbon monoxide of about 1 atm, solubilities in acetic acid were measured by Just (2) at 293.15 K and 298.15 K, and by Skirrow (3) at 298.15 K (2 values). The lower of Skirrow's values is very close to Just's at 298.15 K, which may be accepted tentatively.

For a partial pressure of carbon monoxide of 5.06 MPa Granzhan (4) measured the solubility in acetic acid at 298 K and 348 K, but the values appear to be too low and should be rejected. Dake and Chaudhari (5) measured the solubility over 298-448 K at partial pressures of 2-6 MPa, and their values appear to be of the correct magnitude. Choosing the same temperatures and pressures for comparison, their values are more than twice as large as Granzhan's and about 14% lower than those from Just and Skirrow by extrapolation. It may be that their solvent sample was not totally free from water which would lower the solubility. The data are part of a study of the solubility of carbon monoxide in mixtures of water and acetic acid, and appear in the water + organic solvent section of this volume.

Skirrow (3) measured the solubility of carbon monoxide also in solvents consisting of acetic acid mixed with chloroform aniline or nitrobenzene. Data are collected in this section, and comments made above concerning Skirrow's work on solvent mixtures containing acetone also apply here.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Ketones, acids, esters, ethers.

EVALUATOR:

Robert W. Cargill.
Department of Molecular
and Life Sciences,
Dundee Institute of Technology,
Bell Street, Dundee DD1 1HG, U.K.

March 1989

CRITICAL EVALUATION:

Granzhan (4) also measured the solubility at 298 K and 348 K of carbon monoxide at 5.06 MPa in solvents which were binary mixtures of acetic acid, methanol, and methyl acetate. The values are classed as doubtful.

Propionic (propanoic) acid [79-09-4]

Dake and Chaudhari (5) studied the solubility of carbon monoxide at 2-6 MPa also in mixtures of propionic acid and water at 298-448 K, and values for carbon monoxide in propionic acid itself are given in the water + organic solvent section of this volume. They may be accepted tentatively, but require confirmation by further measurements.

Methyl acetate [79-20-9]

Horiuti's values (1) at a partial pressure of 1 atm and 194-313 K can again be accepted tentatively. Granzhan's values (4) at a partial pressure of 5.06 MPa and 298-348 K must be taken with great caution. Extrapolation of a value at 298 K from 5.06 MPa to 0.1 MPa for comparison with Horiuti's shows a 17% difference (low). However, part of this may be due to deviations from Henry's law.

Ethyl acetate [141-78-6]; propyl acetate [109-60-4]; isobutyl acetate [110-19-0]; amyl acetate [628-63-7]

The values of Just (2) at 293.15 K and 298.15 K, and of Gjaldback and Andersen (6) at 298.15 K (for propyl acetate only) may be accepted tentatively, but require confirmation. The solubilities show a steady increase as the molecular weights of the esters increase.

Diethyl ether (1-1'oxybisethane) [60-29-7]

Christoff's value (7) at 273.15 K is about 5% lower than that obtained from Horiuti (1) covering 194-293 K. Their values at 283.15 K are within 0.5% of each other. The latter set of data by linear regression gave the smoothing equation and smoothed data which appear on the data sheet, and may be accepted tentatively. However, the experimental value at 293.15K appears to be anomalously low and it was omitted from the linear regression analysis.

1,4 Dioxane [123-91-1]

For this solvent, a paper by Krauss and Gestrich (8) gave the solubility of carbon monoxide at a partial pressure of 1 atm between 288 K and 316 K, in the form of a graph from which numerical data were compiled. Veleckis and Hacker (9) measured the solubility at partial pressures between 5.7 atm and 68 atm over 352-446 K. There are no inconsistencies between them. Each may be accepted tentatively.

- 1. Carbon monoxide; CO; [630-08-0]
- 2. Ketones, acids, esters, ethers

Z. Phys. Chem., Stoechiom. Verwandtschaftsl. 1901, 37, 342-67.

VARIABLES:

T/K = 293.15, 298.15 $p_1/kPa = 101.325 (1 atm)$ PREPARED BY:

M. E. Derrick H. L. Clever

EXPERIMENTAL VALUES:

T/K	Mol Fraction	Bunsen Coefficient α/cm³(STP)cm-³atm-1	Ostwald Coefficient L/cm ³ cm ⁻³
293.15	6.49	0.198	0.2128
298.15	6.72	0.204	0.2225

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) 2-Propanone. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

258.15	7.33		

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a gas buret, a solvent reservoir, and an absorption pipet. The volume of the pipet is determined at various meniscus heights by weighing a quantity of water. The meniscus height is read with a cathetometer.

The dry gas is introduced into the degassed solvent. The gas and solvent are mixed with a magnetic stirrer until saturation. Care is taken to prevent solvent vapor from mixing with the solute gas in the gas buret. The volume of gas is determined from the gas buret readings, the volume of solvent is determined from the meniscus height in the absorption pipet.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by dropping formic acid onto conc. H₂SO₄. The gas was passed through several wash solutions to remove CO₂ and O₂, dried by H₂SO₄ and P₂O₅.
- (2) Acetone. Nippon Pure Chemical Co. or Merck. Extra pure grade. Recrystallized with sodium sulfite and stored over calcium chloride. Fractionated, boiling point (760 mmHg) 56.09°C.

ESTIMATED ERROR:

$$\delta T/K = 0.05$$

The Bunsen coefficient and the mole fraction values were calculated by the compiler assuming ideal gas behavior. The values are adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of the liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the solvent volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) 2-Propanone. Acetic acid.

No information.

ESTIMATED ERROR:

AUXILIARY INFORMATION

METHOD 'APPARATUS / PROCEDURE:

Static method in which the temperature variation of the pressure of a mixture of known composition was measured. The pressure-temperature curve has a change in slope corresponding to a change from a one-phase to a two-phase system. Above data obtained by graphical interpolation. Details of method in ref. (1).

SOURCE AND PURITY OF MATERIALS:

- 1. Purity 99.7 mole per cent.
- 2. Pure grade, distilled.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.2$ (up to 300 °C). ± 0.5 (above 300 °C); $\delta P/MPa = \pm 0.2$.

293.15	4.02	0.157	0.1689
298.15	4.03	0.157	0.1714

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Acetic acid. No information.

ESTIMATED ERROR:

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the liquid volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Acetic acid.
- (3) Trichloromethane.

No information.

ESTIMATED ERROR:

 $\delta L/\text{cm}^3 = \pm 0.001 \text{ (Author)}$

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

a solvent reservoir, and an absorption pipet. The volume of the pipet is determined at various meniscus heights by weighing a quantity of water. The meniscus height is read with a cathetometer.

The dry gas is introduced into the degassed solvent. The gas and solvent are mixed with a magnetic stirrer until saturation. Care is taken to prevent solvent vapor from mixing with the solute gas in the gas buret. The volume of gas is determined from the gas buret readings, the volume of solvent is determined from the meniscus height in the absorption pipet.

SOURCE AND PURITY OF MATERIALS:

- The apparatus consists of a gas buret (1) Carbon monoxide. Prepared by dropping formic acid onto conc. H₂SO₄. The gas was passed through several wash solutions to remove CO_2 and O_2 , dried by H_2SO_4 & P_2O_5
 - (2) Methyl acetate. Merck. Extra pure grade. Dried with P205 Distilled several times. Boiling point (760 mmHg) 57.12°C.

The mole fraction and Ostwald coefficient values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared from formic acid (Merck, analytical reagent), 99.6 - 99.9% CO, the rest being atmospheric air.
- (2) Acetic acid, propyl ester.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Acetic acid, pentyl ester. No information.

ESTIMATED ERROR:

 $\delta L/L = 0.03$ (compiler)

The mole fraction and Bunsen coefficient values were calculated by the compiler assuming ideal gas behavior.

AUXILIARY INFORMATION

METHOD / APPARATUS / PROCEDURE:

The apparatus is an Ostwald type as described by Just (ref 1), and modified by Skirrow (ref 2). The apparatus consists of a thermostated gas buret and an absorption flask.

The modification involves the use of vapor free gas in the gas buret. A correction is made for the vapor pressure of the solvent. A steel capillary tube with a stopcock, which prevents the gas and the solvent vapor ESTIMATED ERROR: from mixing in the buret, is used to connect the absorption flask and the buret.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the author by the action of sulfuric acid on sodium formate.
- (2) Diethyl ether. Merck. Stated to be pure and anhydrous.

 $\delta L/L = \pm 0.03$

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a gas buret, a solvent reservoir, and an absorption pipet. The volume of the pipet is determined at various meniscus heights by weighing a quantity of water. The meniscus height is read with a cathetometer.

The dry gas is introduced into the degassed solvent. The gas and solvent are mixed with a magnetic stirrer until saturation. Care is taken to prevent solvent vapor from mixing with the solute gas in the gas buret. The volume of gas is determined from the gas buret readings, the volume of solvent is determined from the meniscus height in the absorption pipet.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by dropping formic acid onto conc.

 H2SO4. The gas was passed through several wash solutions to remove CO2 and O2. dried by H2SO4 & P2O5
- CO₂ and O₂,dried by H₂SO₄ & P₂O₅.

 (2) Diethyl ether. Merck. "For analysis grade". Stored over sodium amalgam until evolution of gas ceased. Distilled, boiling point constant within 0.01°C.

ESTIMATED ERROR:

$$\delta T/K = 0.05$$

 $\delta x_1/x_1 = 0.01$

COMPONENTS: 1. Carbon monoxide; CO; [630-03-0] Krauss, W.; Gestrich, W. 2. 1,4-Dioxane; C₄H₈O₂; [123-91-1] Chem.-Tech. (Heidelberg) 1977, 6, 513-516. VARIABLES: T/K = 288 - 317 R. W. Cargill

VARIABLES:

$$T/K = 352.8 - 446.6$$

 $p_{\pm}/kPa = 660 - 7113$

PREPARED BY:

H. L. Clever

EXPERIMENTAL VALUES: - given on next page

The data were fitted by the method of least squares to the equation $x_1 = \alpha(T/K) \left(p_1/\text{atm} \right) + \beta(T/K) \left(p_1/\text{atm} \right)^2$ $x_1 = \{2.025 \times 10^{-3} - 0.4974/(T/K)\} \left(p_1/\text{atm} \right) + \{-2.574 \times 10^{-6} + 7.351 \times 10^{-4}/(T/K)\} \left(p_1/\text{atm} \right)^2$ and Henry's constant, $H/\text{atm} = (p_1/\text{atm})/x_1$, by the equation

ln(H/atm) = 5.688 + 594.6/(T/K)

The fugacity coefficient was calculated from the equation $RT\ln(f_1^0/p_1) = Bp_1 + ((C - B^2)/2RT)(p_1)^2$. The CO partial pressure was obtained by subtracting the solvent vapor pressure from the total pressure, $p_1 = p_t - p_2^0$. The 1,4-dioxane vapor pressure was taken from Vinsor, C. G.; Martin, J.J. J. Chem. Eng. Data 1963, 8, 74. The virial coefficients were taken from Michels, A.; Lupton, J. M.; Wassenaar, T.; De Graaf, W. Physica 1952, 18, 121 as $B/cm^3 mol^{-1} = -118.7 + 0.5266(T/K) - 5.261 \times 10^- (T/K)^2$ $C/cm^6 mol^{-2} = 4225 - 12.18(T/K) + 1.208 \times 10^- (T/K)^2$

Parameters of the Krichevsky-Ilinskaya equation (Zh. Fiz. Khim. 1945, 19, 621) are given in the paper. The partial molar thermodynamic properties at infinite dilution are $\Delta \overline{H}_{1}^{\infty}$ /cal mol⁻¹ = 1181, and $\Delta \overline{S}_{1}^{\infty}$ /cal K⁻¹ mol⁻¹ = -11.30.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solvent was degassed by the method of Battino, et al. (ref 1).

The solubility was measured in a 2 liter stainless steel autoclave equiped with a magnetically driven stirrer, pressure transducer, thermocouple system, leads to gas and liquid, and a 0.125 in diameter liquid sampling tube.

One liter of degassed liquid is placed into the autoclave. The system is pressurized with CO and brought to the measurement temperature. The system is stirred at 250 rpm until the total pressure remains constant for one hour. Stirring time ranges from 1 h at 173 °C to 8 h at 80 °C. The liquid sampling line is purged

The liquid sampling line is purged by removing and discarding the first 6 cm³, then an 8 to 12 cm³ sample is collected in a previously evacuated buret system. The gas flashes out of solution and is measured at one atm pressure. The buret system is similar to the one described by Wiebe et al. (ref 2).

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson Co., Inc. Stated to be better than 99.99 percent.
- (2) 1,4-Dioxane. Aldrich Chemical Co. Spectrophotometric grade, stated to be better than 99 percent.

ESTIMATED ERROR:

a 1,4-Dioxane vapor pressures from literature equation in Vinsor, C. G.; Martin, J. J. J. Chem. Eng. Data 1963, 8, 74.

- 1. Carbon monoxide; CO; [630-08-0]
- Organic compounds containing halogen

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology, Bell Street, Dundee DD1 1HG, U.K.

March 1989

CRITICAL EVALUATION:

Some fluoro-, chloro-, and bromo - compounds are included in this section as solvents for carbon monoxide at partial pressures around 1 atm. There is also one set of data for the solubility of carbon monoxide at 0.5-0.8 MPa partial pressure, in a fluorinated polyether.

1.	Freons:	Trifluoromethane;	CHF ₃ ;	[75-46-7]
		Tetrafluoromethane;	CF ₄ ;	[75-73-0]
		Chlorotrifluoromethane;	cclf ₃ ;	[75-72-9]
		Chlorodifluoromethane;	CHClF ₂ ;	[75-45-6]
		Dichlorodifluoromethane;	CCl ₂ F ₂ ;	[75-71-8]

The solubility of carbon monoxide in these five freons has been measured by Leites et al. (1, 2) at low temperatures, down to 93 K in some cases. The solubilities are high, and the values recorded on the data sheets were abstracted from graphs in the original papers. This, and the unspecified error in the measurements themselves, means that these, the only data for these solvents, should be used only with some caution until some confirmatory evidence becomes available.

Tetrachloromethane; CCl₄; [56-23-5]

The measurements of Horiuti (3) are within about 1% of the more recent ones by Tominaga $et\ al.$ (4) over the common temperature range $280-313\ K.$ In this range, the values given on the data sheets are recommended. The values at the lower and higher temperatures, given by Horiuti may be taken as tentative, and the smoothing equation given on data sheet used with some confidence over $253-333\ K.$

Trichloromethane; CHCl₃; [67-66-3]

Skirrow's two values (5) are about 5% higher than Just's (6) at 298.15 K. All these data for this system can only be used with caution, and confirmation is obviously necessary sometime in the future.

- 4. 1, 2 Dichloroethane; $C_2H_4Cl_2$; [107-06-2]
 - 1, 2 Dibromoethane; $C_2H_4Br_2$; [106-93-4]

The data due to Skirrow (5) and Gjaldback and Andersen (7) respectively on these two solvents at 298.15 K may be accepted tentatively until some further measurements are made. In fact the very recent measurement by Lühring and Schumpe (12) on 1,2-dichloroethane at 293.2 K is 1% lower than Skirrow's value at 298.15 K, and whilst the evaluator believes it to be somewhat low, it may be taken tentatively also.

5. Hexadecafluoroheptane; C₇F₁₆; [335-57-9]

Hexafluorobenzene; C_6F_6 ; [392-56-3]

The solubilities of carbon monoxide at temperatures around 298.1 K in these perfluorinated solvents, measured by Gjaldback (8) and by Evans and Battino (9) respectively, are probably quite reliable due to the high quality of the experimental work of these authors. Obviously further confirmation is highly desirable. It is noteworthy that these solubilities are four to five times higher than for the other solvents considered in this section.

- 1. Carbon monoxide; CO; [630-08-0]
- Organic compounds containing halogen

EVALUATOR:

Robert W. Cargill,
Department of Molecular
and Life Sciences,
Dundee Institute of Technology,
Bell Street, Dundee DD1 1HG, U.K.

March 1989

CRITICAL EVALUATION:

6. Chlorobenzene; C₆H₅Cl; [108-90-7]

The measurements of Horiuti (3) on chlorobenzene as solvent from 232 K to 353 K are likely to be quite reliable, like the rest of his solubility work. The data and the smoothing equation given on the data sheet can be accepted tentatively.

7. Trifluoroacetic acid; CF₃CO₂H; [76-05-1]

Fujioca and Cady (10) measured the solubility of carbon monoxide in trifluoroacetic acid, at a partial pressure of 646 mmHg (0.85 bar) and 299 K, by a volumetric technique. They reported an Ostwald coefficient of 0.0. This measurement would need to be quantified more carefully, and no data sheet has been prepared from this work.

8. Fomblin; perfluorinated polyether; [25038-02-2]

The measurements of Matsumato and Satterfield (11) on the solubility of carbon monoxide, at a partial pressure of $0.5-0.8\,$ MPa and at $473-533\,$ K, have been included in this section. The data may be accepted provisionally until, as with most other halogen containing solvents for carbon monoxide, further experimental evidence is available.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a gas buret, a solvent reservoir, and an absorption pipet. The volume of the pipet is determined at various meniscus heights by weighing a quantity of water. The meniscus height is read with a cathetometer.

The dry gas is introduced into the degassed solvent. The gas and solvent are mixed with a magnetic stirrer until saturation. Care is taken to prevent solvent vapor from mixing with the solute gas in the gas buret. The volume of gas is determined from the gas buret readings, the volume of solvent is determined from the meniscus height in the absorption pipet.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by dropping formic acid onto conc. H₂SO₄. The gas was passed through several wash solutions to remove CO₂ and O₂,dried by H₂SO₄ & P₂O₅.
- (2) Tetrachloromethane. Kahlbaum. Dried over P₂O₅ and distilled. Boiling point (760 mmHg) 76.74°C.

ESTIMATED ERROR:

Smoothed data: for 282.7 < T/K < 318.2,

 $\ln L_{2,1} = -0.57915 - 281.50 (K/T)$

 $\ln H_{2,1} = 18.2607 + 93.84 (K/T)$

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Equilibrium between the gas and the solvent was achieved by stirring in an apparatus after the design of Ben Naim and Baer (1). Pressure control and measurement of gas volume was microprocessor driven. Mercury is absent from the apparatus.

Solvent was degassed by vacuum pumping and stirring (2).

Temperature control to ± 0.1 K was in an air thermostat.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson Co., purity >99.8%.
- (2) Tetrachloromethane. Fisher certified 99 mol % pure, redistilled, protected from light.

ESTIMATED ERROR:

 $\delta L/L = \pm 0.01$ $\delta T/K = \pm 0.1$

2	98.15	6.44	0.179	0.1954

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Trichloromethane. No information.

ESTIMATED ERROR:

The Bunsen coefficient and the mole fraction values were calculated by the compiler assuming ideal gas behavior. The values are adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of the liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the solvent volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Trichloromethane.
 1,2-Dichloroethane.

No information.

ESTIMATED ERROR:

 $\delta L/cm^3 = \pm 0.001$

The Bunsen coefficients were calculated by the compiler.

The solubility values were adjusted to an oxygen partial pressure of 101.325 kPa (1 atm) by Henry's law.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The solubility apparatus is based on the design of Morrison and Billett (1) and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus is that described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is intermittently applied through a liquid N₂ trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass helical tube containing solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

CRITICAL EVALUATION:

Carbon disulfide [75-15-0]

The disagreement between the three sets of data which are available for carbon monoxide at a partial pressure of 101.3 kPa dissolving in carbon disulfide, makes it impossible to recommend any values even tentatively. Just's values (1) at 293.15 K and 298.15 K correspond closely with one of Skirrow's (2) at 298.15 K, but Skirrow's second value at this temperature is about 16% higher. The more recent work of Gjaldbaek (3) gives values at 298.15 K which are about 70% higher. It may be that the solvent used by Gjaldbaek was of significantly greater purity. Further measurements are necessary to resolve the discrepancy. In this context it is worth noting that for the solubility of nitrogen in this solvent, the values given by Just (1) were about 35% lower than those given by Gjaldbaek and Hildebrand (5) at these temperatures.

Skirrow's paper (2) contains data on the solubility of carbon monoxide in mixtures of carbon disulfide and 1,2-dichloroethane [107-06-2]. These solubilities appear to go through a maximum as the composition of the solvent changes through about 50% by volume. The data, however, need to be read with caution in the absence of any corroborating evidence. The solubility in mixtures of carbon disulfide and acetone, also due to Skirrow, may be referred to in an earlier section of this volume dealing with acetone.

Hydrogen sulfide [7783-06-4]

The work of Fredenslund and Mollerup (4) at 203-293 K and 0.15-24 MPa may be consulted for the carbon monoxide - hydrogen sulfide system. There is no reason to reject the data, but confirmation is necessary by some additional work on this system.

293.15	2.03	0.0756	0.08112
298.15	2.06	0.0762	0.08314

The author measured the Ostwald coefficient at a pressure of about 746 mmHg. The compiler assumed the Ostwald coefficient to be independent of pressure, and calculated the mole fraction and Bunsen coefficient values at 101.325 kPa (1 atm) partial pressure of the gas.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald apparatus as modified by Timofejew (1), and Steiner (2) is used. The apparatus consists of a gas buret, an absorption flask, and a mercury manometer. The system is thermostated with a water jacket.

The gas is introduced into the degassed liquid. The gas volume absorbed is determined by the gas buret. The solvent volume is determined at the end of the experiment by pouring the solvent into a graduated flask.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the decomposition of oxalic acid by sulfuric acid and heat. Carbon dioxide was removed by passing the gas through a KOH solution.
- (2) Carbon disulfide. No information.

ESTIMATED ERROR:

The Bunsen coefficient and the mole fraction values were calculated by the compiler assuming ideal gas behavior. The values are adjusted to a carbon monoxide partial pressure of 101.325 kPa (1 atm) assuming Henry's law is obeyed.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

An Ostwald type apparatus similar to that described by Just (1) was used.

The apparatus consists of a waterjacketed gas buret, a manometer, and an absorption flask.

The volume of dry gas absorbed by a known volume of the liquid is obtained as the difference between the initial and final gas buret readings at atmospheric pressure.

The absorbed gas volume is calculated at the partial pressure of the solute gas over the liquid by means of the previously measured liquid vapor pressure. The ratio of the calculated gas volume to the solvent volume is the Ostwald coefficient.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by the action of sulfuric acid and heat on oxalic acid. The gas was passed through KOH to remove CO₂.
- (2) Carbon disulfide. No information.

ESTIMATED ERROR:

Bell Street, Dundee DD1 1HG, U.K.

February 1989

CRITICAL EVALUATION:

Data have been published on the solubility of carbon monoxide in nine solvents of this class. Most refer to temperatures near 298 K and partial pressures of about 1 bar. In only a few cases has it been possible to compare values from different sources, so that a fully critical evaluation has not always been possible.

- N-Ethylethanamine (diethylamine); C_AH₁₁N; [109-89-7]
- 2. N, N-Diethylethanamine (triethylamine); $C_6H_{15}N$; [121-44-8]

Taqui Khan and Halligudi (1) measured the solubility of carbon monoxide in these amines, and in various mixtures of each of them with water, at partial pressures near 3.2 MPa and 343-373 K. The data sheets to consult are in the (water + organic solvent) section of this volume. The experimental values may be used with caution. They need to be confirmed by further measurements since the data on carbon monoxide in water from the same set of experiments showed some discrepancies from other published data. (See evaluation of the high pressure solubility of carbon monoxide in water).

Benzeneamine (aniline); C₆H₇N; [62-53-3]

Just (2), Skirrow (3), and Gjalbaek and Andersen (4) have provided data on the solubility of carbon monoxide in benzeneamine at a partial pressure of 101.3 kPa and at 298.15 K. Gjaldbaek and Andersen's value may be more accurate due to their careful purification of the solvent, but it is about 5% lower than the others which agree within 1%. A mol fraction solubility of 1.94 x 10^{-4} is recommended, with a possible error of \pm 2%. Just's value at 293.15 K may be accepted provisionally.

4. Nitrobenzene; C₆H₅NO₂; [98-95-3]

At 298.15 K and a partial pressure of 101.3 kPa, data from the same three laboratories may again be compared (2, 3, 4). Once more the value of Gjaldbaek and Andersen is about 5% lower than the other two values which agree closely. However, given that the solvent used by Gjaldbaek and Andersen was thoroughly purified, the average of their six measurements is recommended for this system, $x_1 = 3.73 \times 10^{-4}$. Just's value at 293.15 K may be accepted provisionally.

5. Pyridine; C₅H₅N; [110-86-1]

Gjaldbaek and Andersen's (4) value at 298.15 K and 101.3 kPa may be accepted tentatively. The data of Vasilieva et al (5) for a partial pressure of carbon monoxide of 5-30 MPa and at 313-513 K have to be taken with some caution in the absence of confirmatory evidence. However, extrapolation of those data at 313.2 K from 5 MPa to 0.1 MPa gives a value similar to Gjaldbaek and Andersen's experimental one.

6. 1,1-Dimethylhydrazine; $N_2H_2(CH_3)_2$ [57-14-7]

Chang et al.(6) have given mol fraction solubilities for carbon monoxide in this solvent at 253-298 K and partial pressures in the range 1-2 bar. Their data are the only ones for this system. Although there is no reason to doubt their validity, some confirmation would be highly desirable.

- 1. Carbon monoxide; CO; [630-08-0]
- Organic compounds containing nitrogen

EVALUATOR:

Robert W. Cargill, Department of Molecular and Life Sciences, Dundee Institute of Technology, Bell Street, Dundee, DD1 1HG, U.K.

February 1989

CRITICAL EVALUATION:

- 7. Propanenitrile; C₃H₅N; [107-12-0]
- 8. Benzeneacetonitrile (benzyl cyanide); C₂H₇N; [140-29-4]

The values at 298.15 K and a partial pressure of 101.3 kPa for each of these solvents given by Gjaldbaek and Andersen (4) may be taken tentatively until some further evidence is available.

9. N,N-Dimethylformamide; C₃H₇NO; [68-12-2]

The data of Haidegger et~al. (7) at 278.15, 293.15, and 313.15 K show some irregular variations with pressure, and a large possible error exists. They should be used only with very great caution.

The mole fraction and Ostwald coefficient values were calculated by the compiler.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus consists of a calibrated all-glass manometer and bulb enclosed in an air thermostat. The solvent is added and degassed in the apparatus. The gas is added. The apparatus and contents are shaken until equilibrium is attained. Mercury is used for calibration and as the confining liquid.

The absorbed volume of gas is calculated from the initial and final amounts of gas, both saturated with solvent vapor. The amount of solvent is determined by the weight of displaced mercury. Further details are in the references (1, 2).

The mole fraction values are at one atm pressure assuming Henry's law is obeyed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared from formic acid (Merck, analytical reagent). 99.6 - 99.9% CO, the rest being atmospheric air.
- (2) Nitrobenzene. Purified by fractional freezing and by fractional
 distillation in vacuum.

CRITICAL EVALUATION:

A number of workers have measured the solubility of carbon monoxide in a variety of fluids of biological origin. In view of the importance of monitoring and understanding the toxicity of carbon monoxide it is surprising that more work has not been done in this area. In fact the data available on most of these solvents are rather scarce and fragmentary, and the experimental conditions are subject to such variation that comparison to produce a meaningful evaluation is very difficult. Data have been compiled for the following solvents. In most cases the partial pressure of carbon monoxide is around 1 atm.

1. Olive oil

Battino et al. (1) and Power and Stegall (2) have provided data covering 298-328 K and 285 - 310 K respectively. The discrepancy between the two sets of data is quite small (about 2%) and may be due to differences in the olive oil samples used. The values from Battino et al. (1) are recommended.

2. Gelatin in water

Shkol'nikova's data (3) for solutions of 1-10% by weight of gelatin in water as solvent for carbon monoxide between $283\ K$ and $313\ K$ appear to be of the correct magnitude and follow the normal trends.

3. Blood, serum, plasma

Findlay and Creighton (4), O'Brien and Parker (5), Power (6), and Power and Stegall (2) measured the solubility of carbon monoxide in human and animal blood and blood components at temperatures in the range 283 - 313 K. Several values are available for 310.15K, the normal physiological temperature for humans. Shkol'nikova (3) measured solubilities in 0.5 - 2.9 weight percent solutions of serum albumin in water.

Allowing for the very real possibility of variation between solvent samples and their preparation, and some differences in experimental conditions, the values in most cases confirm one another. Individual data sheets may be consulted for values which may be taken tentatively. The only set of data which deviates considerably from the others is that for deaerated ox serum due to Findlay and Creighton (4). At 754 mmHg pressure, their solubility value appears to be about ten times too small. Data from O'Brien and Parker (5) are to be preferred for this system.

For blood itself, two complementary sets of data are available; (i) from Findlay and Creighton (4) on untreated blood, and (ii) from Power (6) on blood in which the formation of carboxyhemoglobin is prevented by the addition of specific salts. According to these data, carbon monoxide is about five times less soluble in the inhibited sample than in natural blood. The solubility in serum and plasma is similarly about five times smaller. Findlay and Creighton's data were obtained over partial pressures of carbon monoxide between 0.1 and 0.2 MPa and show clearly that Henry's law is not obeyed. All this is evidence for the special interaction of carbon monoxide with hemoglobin in blood, and its role in the toxicity process. One of the earliest studies on the interaction of carbon monoxide with blood was by Hufner and Kulz (7), but no data sheet was compiled from their work because of uncertainties in experimental conditions.

4. Pulmonary and placental tissue

Power's data (6) on human lung tissue and sheep placental tissue at 310.15 K and 45 - 96 kPa partial pressure of carbon monoxide may be taken tentatively, noting again that inhibitors to the formation of carboxyhemoglobin were added to the solvent samples, and that the results have an appropriate correction factor applied to them.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus is based on the design by Morrison and Billett (1) and the version used is a modification of the apparatus of Clever, Battino, Saylor and Gross (2).

Degassing. The solvent is sprayed into an evacuated chamber of an all glass apparatus; it is stirred and heated until the pressure drops to the vapor pressure of the liquid. Solubility Determination. The degassed liquid passes in a thin film down a glass spiral tube at a total pressure of one atm of solute gas plus solvent vapor. The gas absorbed is measured in the attached buret system, and the solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Linde Co. The minimum volume per cent purity is 99.5.

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Gas buret and adsorption pipet similar to that of Geffcken (1) except that the manometer tube was longer to give the higher pressures.

SOURCE AND PURITY OF MATERIALS:

- 1. Obtained by heating pure potassium ferrocyanide with conc. sulfuric acid.
- 2. Obtained from slaughter house. Deaerated samples kept under a reduced pressure of ~2 kPa for one hour.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.1;$ $\delta S/S = \pm 2%$ (estimated by compiler).

- 1. Geffcken, G.
 - Z. Phys. Chem.
 - 1904, 49, 257.

COMPONENTS: 1. Carbon monoxide; CO; [630-08-0]	ORIGINAL MEASUREMENTS: O'Brien, H.R.; Parker, W.L.
2. Beef serum (ox serum)	J. Biol. Chem. 1922, 50, 289-300.

AUXILIARY INFORMATION

METHOD / APPARATUS / PROCEDURE:

Gas was bubbled through a sample of serum, equilibrated in a thermostat, for 15 minutes, at atmospheric pressure. Frothing was prevented by adding a drop of caprylic alcohol. Gas extracted from serum was analysed in a Van Slyke apparatus under standard conditions.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Made by dropping formic acid into conc. sulfuric acid at 150°C; washed through potassium hydroxide solution, stored over water.
- (2) Beef serum. Blood from slaughter house clotted then centrifuged, serum poured off.

CRITICAL EVALUATION:

Carbon dioxide [124-38-9]

The work of Kaminishi et al.(1) is complemented by that of Christiansen et al.(2) on the solubility of carbon monoxide in carbon dioxide at pressures of $0.7-14.1\,$ MPa between 223 K and 283 K. There are no serious contradictions between the two sets of data, and each may be accepted tentatively for the actual temperatures and pressures quoted on the data sheets.

The paper by Christiansen et al. (2) also provided data on the three-component system, carbon monoxide, methane [74-82-8], carbon dioxide, at 223.15 K and 253.15 K and pressures around 3.4 MPa and 7 MPa. The given values may also be accepted tentatively pending other investigations of this system. A similar comment may be made about the data from Yokoyama et al. (3) on the carbon monoxide, hydrogen [1333-74-0], carbon dioxide system, at 253-303 K and 4-9 MPa.

Hydrogen fluoride [7664-39-3]; Boron trifluoride [7637-07-2]

Kudo and Sugita (4) published a study of the solubility of carbon monoxide in hydrogen fluoride at 253-313 K and 1.57-30.5 MPa, and of the three-component system, carbon monoxide, hydrogen fluoride, boron trifluoride, at 273.1 K. Their published paper contains only graphs of their results, but on request, N. Sugita kindly supplied the original numerical data which now appear on the data sheet. The work appears to have been carried out carefully with high purity materials, and the values may be accepted tentatively meantime.

Octamethylcyclotetrasiloxane [556-67-2]

The data of Wilcock et al. (5) for this solvent may be accepted tentatively for carbon monoxide at a partial pressure of 1 atm and temperature 292-313 K. The data sheet contains a smoothing equation which may be used within the limits stated.

Triphenylphosphine [603-35-0]

Herman et al.(6) give the mol fraction solubility of carbon monoxide in triphenylphosphine to be 0.032 at 363.2, 378.2, and 393.2 K and pressures between 5 MPa and 6 MPa. These values are given with a possible error of 5% and require further confirmation

AUXILIARY INFORMATION

METHOD /APPARATUS / PROCEDURE:

Carbon monoxide was charged and stirred into a stainless-steel autoclave containing the solvent, in a thermostat bath.

After equilibrium was reached, stirring was stopped and a sample of the solution was extracted from the bottom of the autoclave into icewater.

After warming to room temperature, the volume of liberated carbon monoxide was measured $(0.3 - 1.2 \text{ dm}^3)$.

The aqueous hydrofluoric acid solutions were analysed chemically.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Prepared by action of hot sulphuric acid on formic acid; purity >99%, by gas chromatography.
- (2) Hydrogen fluoride. Osaka Kinzoku Works, Japan; purity >99.7%, by electrical conductivity.

ESTIMATED ERROR:

 $\delta T/K = \pm 0.5$

 $\delta x_1/x_1 = \pm 0.02$

REFERENCES:

298.42	3.257	0.2345	0.2562
313.12	3.269	0.2313	0.2651

The solubility values were adjusted to a gas partial pressure of $101.325 \ \mathrm{kPa}$ by Henry's law.

The Bunsen coefficients were calculated by the compiler.

Smoothed Data: For use between 292.15 and 313.12 K.

 $\ln x_1 = -5.6067 + 0.3635/(T/100K)$

The standard error about the regression line 6.33 x 10^{-6} .

T/K	Mol Fraction 10 3 x 1
298.15	3.252
308.15	3.264

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The apparatus is based on the design of Morrison and Billett (1), and the version used is described by Battino, Evans, and Danforth (2). The degassing apparatus and procedure are described by Battino, Banzhof, Bogan, and Wilhelm (3).

Degassing. Up to 500 cm³ of solvent is placed in a flask of such size that the liquid is about 4 cm deep. The liquid is rapidly stirred, and vacuum is applied intermittently through a liquid N2 trap until the permanent gas residual pressure drops to 5 microns.

Solubility Determination. The degassed solvent is passed in a thin film down a glass spiral tube containing the solute gas plus the solvent vapor at a total pressure of one atm. The volume of gas absorbed is found by difference between the initial and final volumes in the buret system. The solvent is collected in a tared flask and weighed.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide. Matheson Co. Stated to be 99.5 mole percent minimum purity.
- (2) Octamethylcyclotetrasiloxane. General Electeic Co. Distilled, density at 298.15 K was 0.9500 g cm⁻³.

ESTIMATED ERROR:

 $\delta T/K = 0.03$ $\delta P/mmHg = 0.5$

 $\delta x_1/x_1 = 0.1$

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

A known volume of solvent is equilibrated for about 3 hours with gas under pressure in an autoclave of 300 cm³ capacity at the required temperature.

A known volume of gas-saturated solvent is withdrawn into a gasburette at atmospheric pressure where the volume of gas is measured by displacement of gas-saturated water at constant temperature (1).

Corrections are made for vapour pressures of solvent mixtures, and for the solubility of the gas at atmospheric pressure.

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon monoxide: from British Oxygen Co, UK; purity >99.96%.
- (2) n Butylamine: AR grade, twice distilled before use.
- (3) Water: no information.

ESTIMATED ERROR:

 $\delta p_1 = 3 \text{ kPa}$

 $\delta T = 0.1 \text{ K}$ $\delta S = \pm 3\% \text{ (authors)}$

Elcosane
                                                    E68, E69, 82
Ethanamine, N, N-diethyl-
                                                    E261
Ethanamine, N,N-diethyl- (aqueous)
                                                   E38,
Ethanamine, N-ethyl-
                                                   E261
Ethanamine, N-ethyl- (aqueous)
Ethane, 1,1'-oxybis-
Ethane, 1,2-dibromo-
                                                   E38, 46
                                                   E209, 234, 235
E239, 247, 248
E239, 247, 248
Ethane, 1,2-dichloro-
Ethane, 1,2-dichloro- (ternary)
                                                   258
Ethanol
                                                   E152~E153, E155, 164-167,
                                                    E188, E189, 197
Ethanol (aqueous)
                                                    E38, 41
Ethanol (ternary)
                                                    303
N-Ethylethanamine see ethanamine, N-ethyl-
Fischer-Tropsch fractions
                                                    E68, E69, 89, 93-97
Fomblin
                                                    E240, 253
Formamide, N,N-dimethyl-
                                                    E262, 273
Formamide, N,N-dimethyl- (aqueous)
                                                    302
Gelatin (aqueous)
                                                    E274, E275, 278
Heptane
                                                    E48-E50, 53, 54
Heptane, hexafluoro-
                                                    E239, 250
1-Heptanol
                                                    E152, E153, E158, 179
                           see pentane, hexadecafluoro-
Hexadecafluoropentane
Hexadecane
                                                    E48-E50, 60-62
Hexafluorobenzene see benzene, hexafluoro-
Hexane
                                                    E48-E50, 51, 52
1-Hexanol
                                                    E152, E153, E158, 178
Hexatricontane
                                                    62, E68, 87
E274, E275, 285
Human blood
Human plasma
                                                    E274, E275, 282
Human pulmonary tissue
                                                    E274, E275, 287
Human red cell ghosts
Hydrazine, 1,1-dimethyl-
                                                   E274, E275, 286
                                                   E261, 270
Hydrogen (ternary)
                                                    85, 294,
                                                              295
Hydrogen fluoride
                                                    296, 297
Hydrogen fluoride (ternary)
                                                    298
Hydrogen sulfide
                                                   E254, 259, 260
Isodecanol
                                                   E189, 204, 205
Isononenes
                                                   E70, 98, 99
Kerosene A-1
                                                   E50, 65
Lecithin (ternary)
                                                   Elll, 145
Methane
                                                   E67, 72-77
Methane (ternary)
                                                   293
Methane, chlorodifluoro-
                                                   E239, 243
Methane, chlorotrifluoro-
                                                   E239, 242
Methane, dichlorodifluoro-
                                                   E239, 243
```

```
E239, 244, 245
Methane, tetrachloro-
                                                   E239, 241
E239, 246, 247
187, 217, 226
Methane, tetrafluoro-
Methane, trichloro-
Methane, trichloro- (ternary)
Methane, trifluoro-
                                                   E239, 241
                                                   E152-E154, 160-164, E188,
Methanol
                                                   191-195
                                                   E38, 40, 43, E111, 137, 186, 187, 196, 225
Methanol (ternary)
                    see benzene, methyl-
Methylbenzene
                        see cyclohexane, methyl-
Methylcyclohexane
2-Methyl-1-propanol
                         see 1-propanol, 2-methyl-
                           see 2-propanol, 2-methyl-
2-Methyl-2-propanol
Mineral oil
                                                   E111, 135, 146, 214
E111, 138, 148
E111, 139, 216
Naphthalene (ternary)
1-Naphthalenol (ternary)
2-Naphthalenol (ternary)
Nitrobenzene
                     see benzene, nitro-
Nonane
                                                   E48-E50, 56
                                                   E152, E153, E158, 181
1-Nonanol
Octacosane
                                                   62, E68, E69, 83-85
Octamethylcyclotetrasiloxane see cyclotetrasiloxane, octamethyl-
Octane E48-E50, 54, 55, E68, 79-81
                                                   E152, E153, E158, 179, 180
E274, E275, 276, 277
E274, E275, 279
1-Octanol
Olive oil
Ox blood
Ox serum
                                                   E274, E275, 279, 280
l,l'-Oxybisethane
                       see ethane, 1,1'-oxybis-
                                                   E50, 66, E68, E70, 86
Paraffin oil
Pentadecane
                                                   E48, 60
                                                   E48-E50,
Pentane
                                                   E152, E153, E158, 177, 178
E50, 63
1-Pentanol
Petroleum
Phenanthrene
                                                   Elll, 134, 147
Phenanthrene (ternary)
                                                   Elll, 136, 215

SOLUBILITY DATA SERIES

Volume 1	H. L. Clever, Helium and Neon
Volume 2	H. L. Clever, Krypton, Xenon and Radon
Volume 3	M. Salomon, Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate
Volume 4	H. L. Clever, Argon
Volume 5/6	C. L. Young, Hydrogen and Deuterium
Volume 7	R. Battino, Oxygen and Ozone
Volume 8	C L. Young, Oxides of Nitrogen
Volume 9	W. Hayduk, Ethane
Volume 10	R. Battino, Nitrogen and Air
Volume 11	B. Scrosatı and C. A. Vincent, Alkalı Metal, Alkaline Earth Metal and Ammonium Halides, Amide Solvents
Volume 12	C. L. Young, Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides
Volume 13	S. Siekierski, T. Mioduski and M. Salomon, Scandium, Yttrium, Lanthanum and Lanthanide Nitrates
Volume 14	H. Miyamoto, M. Salomon and H. L. Clever, Alkaline Earth Metal Halates
Volume 15	A. F. M. Barton, Alcohols with Water
Volume 16/17	E. Tomlinson and A. Regosz, Antibiotics: 1, β-Lactam Antibiotics
Volume 18	O. Popovych, Tetraphenylborates
Volume 19	C. L. Young, Cumulative Index: Volumes 1–18
Volume 20	A. L. Horvath and F. W. Getzen, Halogenated Benzenes, Toluenes and Phenols with Water
Volume 21	C. L. Young and P. G. T. Fogg, Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents
Volume 22	T. Mioduski and M. Salomon, Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents
Volume 23	T. P. Dirkse, Copper, Silver, Gold and Zinc, Cadmium, Mercury Oxides and Hydroxides
Volume 24	W. Hayduk, Propane, Butane and 2-Methylpropane
Volume 25	C. Hirayama, Z. Galus and C. Guminski, Metals in Mercury
Volume 26	M. R. Masson, H. D. Lutz and B. Engelen, Sulfites, Selenites and Tellurites
Volume 27/28	H. L. Clever and C. L. Young, <i>Methane</i>
Volume 29	H. L. Clever, Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements
Volume 30	H. Mıyamoto and M. Salomon, Alkali Metal Halates, Ammonium Iodate and Iodic Acid
Volume 31	J. Eysseltová and T. P. Dirkse, Alkali Metal Orthophosphates
Volume 32	P. G. T. Fogg and C. L. Young, Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide
Volume 33	P. Franzosini, Molten Alkali Metal Alkanoates
Volume 34	A. N. Paruta and R. Piekos, 4-Aminobenzenesulfonamides. Part I: Non-cyclic Substituents
Volume 35	A. N. Paruta and R. Piekos, 4-Aminobenzenesulfonamides. Part II: 5-Membered Heterocyclic Substituents
Volume 36	A. N. Paruta and R. Piekos, 4-Aminobenzenesulfonamides. Part III: 6-Membered Heterocyclic Substitutents and Miscellaneous Systems
Volume 37	D G. Shaw, Hydrocarbons with Water and Seawater. Part I: Hydrocarbons C₅ to C₁
Volume 38	D. G. Shaw, Hydrocarbons with Water and Seawater. Part II: Hydrocarbons C ₈ to C ₃₆
Volume 39	C. L. Young, Cumulative Index: Volumes 20–38
Volume 40	J. Hala, Halides, Oxyhalides and Salts of Halogen Complexes of Titanium, Zirconium, Hafnium, Vanadium, Niobium and Tantalum
Volume 41	CY. Chan, I. N. Lepeshkov and K. H. Khoo, Alkaline Earth Metal Perchlorates
Volume 42	P. G. T. Fogg and W. Gerrard, Hydrogen Halides in Non-aqueous Solvents
Volume 43	R. W. Cargill, Carbon Monoxide
